How to Use This Guide

This guide uses the following conventions:

- **Front Panel Key**
  This represents a key physically located on the instrument.

- **SOFTKEY**
  This represents a “softkey”, a key whose label is determined by the instrument firmware.

- **Computer Font**
  This represents text displayed on the instrument’s screen, text on a computer display, or a programming command.

**NOTE**
All model numbers and part numbers published in this document are HP/Agilent numbers, unless otherwise specified.
The Installation and Quick Start Guide provides procedures for installing, configuring, and verifying the operation of the analyzer. It also will help you familiarize yourself with the basic operation of the analyzer.

The User’s Guide shows how to make measurements, explains commonly-used features, and tells you how to get the most performance from your analyzer.

The Reference Guide provides reference information, such as specifications, menu maps, and key definitions.

The Programmer’s Guide provides general GPIB programming information, a command reference, and example programs. The Programmer’s Guide contains a CD-ROM with example programs.

The CD-ROM provides the Installation and Quick Start Guide, the User’s Guide, the Reference Guide, and the Programmer’s Guide in PDF format for viewing or printing from a PC.

The Service Guide provides information on calibrating, troubleshooting, and servicing your analyzer. The Service Guide is not part of a standard shipment and is available only as Option 0BW. A CD-ROM with the Service Guide in PDF format is included for viewing or printing from a PC.

   - Using This Chapter ................................................................. 7-2
   - Measurement Process .............................................................. 7-3
     - Step 1. Setting Up the Instrument .................................... 7-3
     - Step 2. Calibrating the Test Setup .................................... 7-3
     - Step 3. Connecting the Device under Test ....................... 7-4
     - Step 4. Taking the Measurement Data .............................. 7-4
     - Step 5. Post-Processing the Measurement Data ............... 7-4
     - Step 6. Transferring the Measurement Data .................... 7-4
   - Programming Examples .......................................................... 7-5
     - Program Information ............................................................ 7-8
     - Analyzer Features Helpful in Developing Programming Routines .................................................. 7-8
   - Measurement Setup Examples .............................................. 7-10
     - Example 1A: Setting Parameters ...................................... 7-10
     - Example 1B: Verifying Parameters .................................... 7-21
   - Measurement Calibration Examples ........................................ 7-23
     - Calibration Kits ................................................................. 7-24
     - Example 2A: Response Calibration .................................... 7-24
     - Example 2B: 1-Port Calibration ........................................... 7-26
     - Example 2C: Enhanced Response Calibration .................... 7-30
     - Example 2D: Full 2-Port Measurement Calibration ............. 7-33
     - Example 2E: Adapter Removal Calibration ......................... 7-38
     - Example 2F: Using Raw Data to Create a Calibration (Simmcal) .................................................. 7-41
     - Example 2G: Take4 — Error Correction Processed on an External PC ............................................ 7-48
   - Measurement Data Transfer Examples ................................... 7-56
     - Trace-Data Formats and Transfers ...................................... 7-56
     - Example 3A: Data Transfer Using Markers ....................... 7-57
Example 3B: Data Transfer Using FORM 4 (ASCII Transfer) ...................... 7-59
Example 3C: Data Transfer Using Floating-Point Numbers .................. 7-62
Example 3D: Data Transfer Using Frequency-Array Information .............. 7-64
Example 3E: Data Transfer Using FORM 1 (Internal-Binary Format) ......... 7-67
Measurement Process Synchronization Examples .................................. 7-69
Status Reporting .................................................................................. 7-69
Example 4A: Using the Error Queue .................................................... 7-70
Example 4B: Generating Interrupts ...................................................... 7-72
Example 4C: Power Meter Calibration .................................................. 7-75
Analyzer System Setup Examples ....................................................... 7-79
Saving and Recalling Instrument States .............................................. 7-79
Example 5A: Using the Learn String .................................................... 7-79
Example 5B: Reading Calibration Data ................................................ 7-81
Example 5C: Saving and Restoring the Analyzer Instrument State .......... 7-84
List-Frequency and Limit-Test Table Examples .................................... 7-87
Using List Frequency Sweep Mode ..................................................... 7-87
Example 6A: Setting Up a List Frequency Table in Stepped List Mode .... 7-88
Example 6B: Setting Up a List Frequency Table in Swept List Mode ....... 7-90
Example 6C: Selecting a Single Segment from a Table of Segments ....... 7-94
Using Limit Lines to Perform PASS/FAIL Tests ................................... 7-96
Example 6D: Setting Up a Limit-Test Table ......................................... 7-96
Example 6E: Performing PASS/FAIL Tests While Tuning ..................... 7-99
Report Generation Examples ............................................................... 7-102
Example 7A: Operation Using Talker/Listener Mode ............................ 7-102
Example 7B: Controlling Peripherals Using Pass-Control Mode .......... 7-104
Example 7C: Printing with the Parallel Port ........................................ 7-107
Example 7D: Plotting to a File and Transferring the File Data to a Plotter 7-109
Example 7E: Reading Plot Files from a Disk ........................................ 7-111
Example 7F: Reading ASCII Disk Files to the Instrument Controller’s Disk File 7-118
Mixer Measurement Example ............................................................... 7-122
Example 8A: Comparison of Two Mixers — Group Delay, Amplitude or Phase 7-122
Limit Line and Data Point Special Functions ....................................... 7-126
Overview ............................................................................................ 7-126
Constants Used Throughout This Document ....................................... 7-131
Output Limit Test Pass/Fail Status Per Limit Segment ....................... 7-131
Output Pass/Fail Status for All Segments ............................................ 7-132
Output Minimum and Maximum Point Per Limit Segment .................. 7-133
Output Minimum and Maximum Point for All Segments ..................... 7-134
Output Data Per Point ......................................................................... 7-137
Output Data Per Range of Points ........................................................ 7-138
Output Limit Pass/Fail by Channel ...................................................... 7-138

A. Preset Conditions
   Preset State ..................................................................................... A-2

B. Command Listings
   Alphabetical List of Commands ...................................................... B-2

**NOTE**
A terminator indicates the end of a command string, and this manual uses a semicolon as the terminator in all syntax examples. The network analyzer also interprets line feeds and GPIB end or identify (EOI) messages as terminators.

Terminators are not necessary for the analyzer to interpret commands correctly, however in the case of a syntax error, the analyzer will attempt to recover at the next terminator. Therefore, it is recommended that you each command include a terminator.

**NOTE**
Because this chapter is an “Alphabetical Command Reference,” the commands have been listed alphabetically, rather than by function, in both the “Syntax” sections and the “Description” sections. Therefore, commands grouped together in the “Syntax” sections, are grouped alphabetically and/or due to common syntax form, not necessarily due to common functionality.

**NOTE**
The softkeys listed in the “Front Panel Equivalents” tables may not be in the first menu viewed when the associated hardkey is pressed. In many cases, more than one key press will be required to locate the softkey. Refer to your analyzer’s reference guide for the exact location of any softkey.

**NOTE**
Some commands that do not have an associated query syntax can be queried by sending the command (without a value) and then sending the `OUTPACTI` command, as in the following example that queries the segment power value:

```
10 OUTPUT 716;"SEGPOWER;OUTPACTI;"
```

Many of the commands that do have a listed query syntax can also be queried in this manner.
AB

Syntax

AB; or AB?;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB</td>
<td>Measures and displays A/B on the active channel.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB</td>
<td>Meas</td>
<td>A/B</td>
</tr>
</tbody>
</table>

ADAP1

Syntax

ADAP1<num>[S]; or ADAP1?;

NOTE This command only applies to ES model analyzers.

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADAP1</td>
<td>Sets adapter electrical delay.</td>
<td>±10 seconds</td>
<td>&lt;num&gt;&lt;F&gt;</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADAP1</td>
<td>Cal</td>
<td>ADAPTER DELAY</td>
</tr>
</tbody>
</table>
ADDRLSRC\(^1\)

- **Description**: LO source GPIB address. See also TITTPERI.
- **Range**: integers 0–30
- **Query Response**: \(<\text{num}\>_{LF}\)

### ADDRPRIN

- **Description**: Printer GPIB address.
- **Range**: integers 0–30
- **Query Response**: \(<\text{num}\>_{LF}\)

---

1. This command only applies to 8753ET/ES analyzers.

### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDRCONT</td>
<td>Local</td>
<td>ADDRESS: CONTROLLER</td>
</tr>
<tr>
<td>ADDRDISC</td>
<td>Local</td>
<td>ADDRESS: DISK</td>

</tbody>
</table>

---
### ADPT

#### Syntax

```
ADPT<COAX|WAVE>; or ADPT<COAX|WAVE>?
```

#### Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADPTCOAX</td>
<td>Sets adapter to coaxial.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>ADPTWAVE</td>
<td>Sets adapter to waveguide</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

#### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADPTCOAX</td>
<td>Cal</td>
<td>ADAPTER COAX</td>
</tr>
<tr>
<td>ADPTWAVE</td>
<td>Cal</td>
<td>ADAPTER WAVEGUIDE</td>
</tr>
</tbody>
</table>

### ALC

#### Syntax

```
ALC<ON|OFF>; or ALC?
```

#### Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALC</td>
<td>ALC control. For service use only.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

#### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALC</td>
<td>System</td>
<td>ALC ON OFF</td>
</tr>
</tbody>
</table>
**ALTAB**

**Syntax**

ALTAB; or ALTAB?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTAB</td>
<td>Places the analyzer in the alternate inputs measurement mode, where A and B measurements are made on alternate sweeps. See also “CHOPAB.”</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTAB</td>
<td>Cal</td>
<td>ALTERNATE A and B ¹</td>
</tr>
<tr>
<td>ALTAB</td>
<td>Cal</td>
<td>ALTERNATE RFL/TRAN ²</td>
</tr>
</tbody>
</table>

¹. ES models only.
². ET models only.
**ANAB**

**Syntax**

ANAB<ON|OFF>; or ANAB?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANAB</td>
<td>Enables and disables the analog bus for service use.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANAB</td>
<td>System</td>
<td>ANALOG BUS ON OFF</td>
</tr>
</tbody>
</table>
ANAI

Syntax

ANAI<num>; or ANAI?;
ANAI; or ANAI?;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANAI&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Measures and displays the data at the auxiliary input (ANALOG IN).</td>
<td>integers 1–31</td>
<td>$&lt;0</td>
</tr>
<tr>
<td>ANAI&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Measures and displays the data at the auxiliary input (ANALOG IN).</td>
<td>N/A</td>
<td>$&lt;0</td>
</tr>
</tbody>
</table>

1. When the analog bus is enabled (ANABON), this command requires that the complementary information ($<num>$) be sent.
2. When the analog bus is disabled (ANABOFF), this command does not require the $<num>$ parameter.

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANAI</td>
<td>[Meas]</td>
<td>ANALOG IN Aux Input</td>
</tr>
</tbody>
</table>
AR

**Syntax**

AR; or AR?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>AR</td>
<td>Measures and displays A/R on the active channel.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>AR</td>
<td>Meas</td>
<td>A/R</td>
</tr>
</tbody>
</table>

ASEG

**Syntax**

ASEG; or ASEG?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASEG</td>
<td>Uses all segments for list frequency sweep. See also “SSEG.”</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASEG</td>
<td>Sweep Setup</td>
<td>ALL SEGS SWEEP</td>
</tr>
</tbody>
</table>
ASSS

Syntax

`ASSS;`

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASSS</td>
<td>Asserts the sequence status bit to in-turn generate SRQ.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASSS</td>
<td>Seq</td>
<td>ASSERT SRQ</td>
</tr>
</tbody>
</table>
ATT

Syntax

ATT\textless A|B|P1|P2\textgreater \textless \textless num\textgreater \{DB\}; or ATT\textless A|B|P1|P2\textgreater ?;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATTA$^1$</td>
<td>Selects the amount of attenuation at attenuator A.</td>
<td>0–55 dB</td>
<td>\langle num \rangle \downarrow_F &gt;</td>
</tr>
<tr>
<td>ATTB$^1$</td>
<td>Selects the amount of attenuation at attenuator B.</td>
<td>0–55 dB</td>
<td>\langle num \rangle \downarrow_F &gt;</td>
</tr>
<tr>
<td>ATTP$^1$</td>
<td>Selects the amount of attenuation at PORT 1.</td>
<td>0–70 dB</td>
<td>\langle num \rangle \downarrow_F &gt;</td>
</tr>
<tr>
<td>ATTP$^2$</td>
<td>Selects the amount of attenuation at PORT 2.</td>
<td>0–70 dB</td>
<td>\langle num \rangle \downarrow_F &gt;</td>
</tr>
</tbody>
</table>

1. This command only applies to 8720E series analyzers with Option 085.
2. This command only applies to 8753ES Option 011 analyzers.

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATTA$^1$</td>
<td>Power</td>
<td>ATTENUATOR A</td>
</tr>
<tr>
<td>ATTB$^1$</td>
<td>Power</td>
<td>ATTENUATOR B</td>
</tr>
<tr>
<td>ATTP$^1$</td>
<td>Power</td>
<td>ATTENUATOR PORT 1</td>
</tr>
<tr>
<td>ATTP$^2$</td>
<td>Power</td>
<td>ATTENUATOR PORT 2</td>
</tr>
</tbody>
</table>

1. This command only applies to 8720E series analyzers with Option 085.
2. This command only applies to 8753ES Option 011 analyzers.
AUTO

Syntax
AUTO;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO</td>
<td>Auto scale the active channel.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO</td>
<td>[Scale Ref]</td>
<td>[AUTOSCALE]</td>
</tr>
</tbody>
</table>
AUXC

Syntax
AUXC<ON|OFF>; or AUXC?;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUXC</td>
<td>Enables and disables auxiliary channels 3 and 4. OPC-compatible.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUXC</td>
<td>Display</td>
<td>AUX CHAN ON OFF</td>
</tr>
</tbody>
</table>

EXAMPLE

10 OUTPUT 716;"CHAN1;AUXCON;" Turns on channel 3
20 OUTPUT 716;"CHAN2;AUXCON;" Turns on channel 4
AVER

Syntax

AVERFACT<num>; or AVERFACT?;
AVERO<ON|OFF>; or AVERO?;
AVERREST;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVERFACT</td>
<td>Sets the averaging factor on the active channel.</td>
<td>integers 0–999</td>
<td>&lt;num&gt;&lt;F&gt;</td>
</tr>
<tr>
<td>AVERO</td>
<td>Turns averaging on and off on the active channel.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>AVERREST</td>
<td>.Restarts the averaging on the active channel.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVERFACT</td>
<td>Avg</td>
<td>AVERAGING FACTOR</td>
</tr>
<tr>
<td>AVERO</td>
<td>Avg</td>
<td>AVERAGING ON OFF</td>
</tr>
<tr>
<td>AVERREST</td>
<td>Avg</td>
<td>AVERAGING RESTART</td>
</tr>
</tbody>
</table>
## BACI

### Syntax

BACI<num>; or BACI?;

### Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACI</td>
<td>Sets the background intensity of the display.</td>
<td>integers 0–100</td>
<td>&lt;num&gt;&lt;LF&gt;</td>
</tr>
</tbody>
</table>

### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACI</td>
<td>Display</td>
<td>BACKGROUND INTENSITY</td>
</tr>
</tbody>
</table>

## BANDPASS

### Syntax

BANDPASS; or BANDPASS?;

### Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BANDPASS</td>
<td>Selects the time domain bandpass mode.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BANDPASS</td>
<td>System</td>
<td>BANDPASS</td>
</tr>
</tbody>
</table>
**BEEP**

**Syntax**

BEEP<DONE|WARN|FAIL><ON|OFF>;  or  BEEP<DONE|WARN|FAIL>?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPDONE</td>
<td>Causes the analyzer’s warning beeper to sound at the completion of functions such as save, done with calibration standard, and data trace saved.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>BEEPFAIL</td>
<td>Causes the analyzer’s warning beeper to sound in the event of a limit test failure.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>BEEPWARN</td>
<td>Causes the analyzer’s warning beeper to sound when a warning message is generated.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPDONE</td>
<td>Display</td>
<td>BEEP DONE ON OFF</td>
</tr>
<tr>
<td>BEEPFAIL</td>
<td>System</td>
<td>BEEP FAIL ON OFF</td>
</tr>
<tr>
<td>BEEPWARN</td>
<td>Display</td>
<td>BEEP WARN ON OFF</td>
</tr>
</tbody>
</table>
### BLAD

#### Syntax

BLAD<ON|OFF>; or BLAD?;

#### Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLAD</td>
<td>Blanks the display.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

#### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLAD</td>
<td>Display</td>
<td>BLANK DISPLAY</td>
</tr>
</tbody>
</table>

### BR

#### Syntax

BR; or BR?;

#### Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BR</td>
<td>Measures and displays B/R on the active channel.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

#### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BR</td>
<td>Meas</td>
<td>B/R</td>
</tr>
</tbody>
</table>
**BWLIMDB**

**Syntax**

BWLIMDB<num>; or BWLIMDB?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMDB</td>
<td>Enters the N dB Point, the amplitude below the peak that is used to measure the filter’s bandwidth.</td>
<td>0.001 to 300 dB</td>
<td>&lt;num&gt;&lt;LF&gt;</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMDB</td>
<td>System</td>
<td>N DB POINTS</td>
</tr>
</tbody>
</table>

---

**BWLIMDISP**

**Syntax**

BWLIMDISP<ON|OFF>; or BWLIMDISP?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMDISP</td>
<td>Turns the measured bandwidth value in the upper left corner of the display on and off. The measured bandwidth value is displayed near the bandwidth Pass/Wide/Narrow message...</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMDISP</td>
<td>System</td>
<td>BW DISPLAY on OFF</td>
</tr>
</tbody>
</table>
**BWLIMMAX**

**Syntax**

BWLIMMAX<num>[HZ|KHZ|MHZ|GHZ]; or BWLIMMAX?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMMAX</td>
<td>Enters the maximum bandwidth value. If the measured bandwidth is greater than this value, the filter fails the bandwidth test.</td>
<td>stimulus range(^1)</td>
<td>(&lt;\text{num}&gt;_{LF})</td>
</tr>
</tbody>
</table>

1. Refer to “Preset State and Memory Allocation” in your analyzer’s reference guide.

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMMAX</td>
<td><strong>System</strong></td>
<td><strong>MAXIMUM BANDWIDTH</strong></td>
</tr>
</tbody>
</table>

---

**BWLIMMIN**

**Syntax**

BWLIMMIN<num>[HZ|KHZ|MHZ|GHZ]; or BWLIMMIN?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMMIN</td>
<td>Enters the minimum bandwidth value. If the measured bandwidth is less than this value, the filter fails the bandwidth test.</td>
<td>stimulus range(^1)</td>
<td>(&lt;\text{num}&gt;_{LF})</td>
</tr>
</tbody>
</table>

1. Refer to “Preset State and Memory Allocation” in your analyzer’s reference guide.

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMMIN</td>
<td><strong>System</strong></td>
<td><strong>MINIMUM BANDWIDTH</strong></td>
</tr>
</tbody>
</table>
BWLIMSTAT

Syntax

BWLIMSTAT;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMSTAT</td>
<td>Returns the results of the bandwidth test. A returned value of 0 indicates that the filter passed the bandwidth test. A returned value of −1 indicates that the filter failed the bandwidth test because it is narrower than the bandwidth limit. A returned value of 1 indicates that the filter failed the bandwidth test because it is wider than the bandwidth limit.</td>
<td>N/A</td>
<td>&lt;-1</td>
</tr>
</tbody>
</table>

No Front Panel Equivalents

GPIB only: no front panel equivalent.

BWLIMTEST

Syntax

BWLIMTEST<ON|OFF>; or BWLIMTEST?;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>BWLIMTEST</td>
<td>Turns the bandwidth test on and off.</td>
<td>N/A</td>
<td>&lt;-0</td>
</tr>
</tbody>

<tbody>
<tr>
<td>CLAD</td>
<td>Cal</td>
<td>SPECIFY CLASS DONE</td>
</tr>
</tbody>
</table>
CLASS

Syntax

CLASS<11A|11B|11C|22A|22B|22C>;

Description

These commands call reflection standard classes during a calibration sequence. If only one standard is in the class, it is measured. If there is more than one, the standard being used must be selected with STAN<A|B|C|D|E|F|G>. If there is only one standard in the class, these commands are OPC-compatible.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS11A</td>
<td>S11A: S11 (forward reflection) 1-port, open</td>

CONV

Syntax

CONV<1DS|OFF|YREF|YTRA|ZREF|ZTRA>; or CONV<1DS|OFF|YREF|YTRA|ZREF|ZTRA>?;

Description

These 6 commands convert the S-parameter data to:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONV1DS</td>
<td>Inverted S-parameters.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>CONVOFF</td>
<td>Turns S-parameter conversion off.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>CONVYREF</td>
<td>Y:reflection (admittance).</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>CONVYTRA</td>
<td>Y:transmission (admittance).</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>CONVZREF</td>
<td>Z:reflection (impedance).</td>

<td></td>
<td>COUPLED / UNCOUPLED</td>
</tr>
</tbody>
</table>
CSWI

Syntax

CSWI<ON|OFF>; or CSWI?;

NOTE These commands only apply to ES models.

Description

See also “TSSWI” on page 1-267.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSWION</td>
<td>Selects test set continuous switching. When continuous switching is on, the analyzer measures all four S-parameters each time before displaying the data for a full 2-port cal measurement.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>CSWIOFF</td>
<td>Selects test set hold mode. The analyzer measures all four S-parameters once and then measures the desired parameter continuously. This is known as a fast 2-port cal measurement and it is less accurate than a full 2-port calibrated measurement.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>CSWI?</td>

</tr>
<tr>
<td>CSWIOFF</td>
<td>Cal</td>
<td>TESTSET SW HOLD</td>
</tr>
</tbody>
</table>
CWFREQ

Syntax

CWFREQ<num>[HZ|DB];  or  CWFREQ?;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>CWFREQ</td>
<td>Sets the CW frequency for power sweep and CW frequency modes. While the list frequency table segment is being edited, it sets the center frequency of the current segment. See also “MARKCENT.”</td>
<td>stimulus range¹</td>
<td>&lt;num&gt;&lt;LF&gt;</td>
</tr>
</tbody>
</table>

¹. For frequency or power sweeps, refer to “Preset State and Memory Allocation,” in the analyzer’s reference guide. For CW time: 0 to 24 hours. For frequency sweep, transform on: ±1/frequency step. For CW time sweep, transform on: ±1/time step.

FORM

Syntax

FORM<1|2|3|4|5>;

Description

These 5 commands set the data format for array transfers in and out of the instrument:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORM1</td>
<td>The analyzer's internal binary format, 6 bytes-per-data point. The array is preceded by a four-byte header. The first two bytes represent the string &quot;#A&quot;, the standard block header. The second two bytes are an integer representing the number of bytes in the block to follow. FORM1 is best applied when rapid data transfers, not to be modified by the computer nor interpreted by the user, are required.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>FORM2</td>
<td>IEEE 32-bit floating-point format, 4 bytes-per-number, 8 bytes-per-data point. The data is preceded by the same header as in FORM1. Each number consists of a 1-bit sign, an 8-bit biased exponent, and a 23-bit mantissa. FORM2 is the format of choice if your computer is not a PC, but supports single-precision floating-point numbers.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>FORM3</td>
<td>IEEE 64-bit floating-point format, 8 bytes-per-number, 16 bytes-per-data point. The data is preceded by the same header as in FORM1. Each number consists of a 1-bit sign, an 11-bit biased exponent, and a 52-bit mantissa. This format may be used with double-precision floating-point numbers. No additional precision is available in the analyzer data, but FORM3 may be a convenient form for transferring data to your computer.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>FORM4</td>
<td>ASCII floating-point format. The data is transmitted as ASCII numbers, as described in &quot;Output Syntax&quot; on page 4-3. There is no header. The analyzer always uses FORM4 to transfer data that is not related to array transfers (i.e. marker responses and instrument settings). Data is comma delimited.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>FORM5</td>
<td>PC-DOS 32-bit floating-point format with 4 bytes-per-number, 8 bytes-per-data point. The data is preceded by the same header as in FORM1. The byte order is reversed with respect to FORM2 to comply with PC-DOS formats. If you are using a PC-based controller, FORM5 is the most effective format to use.</td>
<td>N/A</td>
<td></td>
</tr>
</tbody>
</table>

Front Panel Equivalents

GPIB only: no front panel equivalent.
FORMAT

Syntax

FORMAT<DOS|LIF>;

Description

These commands define the format to use on disk initializations:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORMATDOS</td>
<td>Selects DOS as the disk format.</td>
<td>N/A</td>

HARM

Syntax

HARM<OFF|SEC|THIR>; or HARM<OFF|SEC|THIR>?;

NOTE  This command only applies to 8753ES/ET analyzers with Option 002.

Description

These commands activate the harmonic measurement mode, Option 002. They are all OPC-compatible:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>HARMOFF</td>
<td>Turns off harmonic mode.</td>
<td>N/A</td>

</tr>
</thead>
<tbody>
<tr>
<td>IDN?</td>
<td>Query only. Outputs the identification string: HEWLETT PACKARD, 87NNEX, xxxxxxxxxx, X.XX where 87NNEX is the model number of the instrument, xxxxxxxxxx is the serial number of the instrument, and X.XX is the firmware revision of the instrument.</td>
<td>N/A</td>
<td>See command description</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

GPIB only: no front panel equivalent.
### IF

#### Syntax

```
IF<BIHIGH|BILOW|LCEQZE|LCNEZE|LTFAIL|LTPASS>;
```

#### Description

These 6 commands branch an executing sequence to a new sequence if the following condition is satisfied.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFBIHIGH</td>
<td>Tests the specified input GPIO bit (see “PARAIN”). If high, invokes the sequence which follows.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>IFBILOW</td>
<td>Tests the specified input GPIO bit (see “PARAIN”). If low, invokes the sequence which follows.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>IFLCEQZE</td>
<td>If loop counter equals zero, then do the sequence that follows.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>IFLCNEZE</td>
<td>If loop counter does not equal zero, then do the sequence that follows.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>IFLTFAIL</td>
<td>If limit test fails, then do sequence that follows.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>IFLTPASS</td>
<td>If limit test passes, then do sequence that follows.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

#### EXAMPLE

To designate the new sequence, each of the following commands must be followed by the `SEQ<num>` command (where `<num>` = 1 through 6). For example:

```
10 INPUT 716;"IFLCEQZE;" If loop counter equals zero, then
20 OUTPUT 716;"SEQ4;" Execute sequence 4
```

Or the new sequence can be designated as part of the command itself. For example:

```
10 OUTPUT 716;"IFLCEQZESEQ4;" If loop counter equals zero, then execute sequence 4
```

INPU

Syntax

INPUCALC<num><array>;  
INPU<CALK|DATA|FORM><array>;  
INPULEAS<learnstring>; or INPULEAS?;  
INPUPMCAL1|2><array>;  
INPURAW<1|2|3|4><array>;

Description

All of these commands (with a few noted exceptions) input an array and require that you set the format for data transfers with the FORM command. All of these commands have an associated output command that is used to transfer data from the analyzer. See “OUTP,” later in this chapter.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>

<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>INPUPMCAL2&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Inputs power meter calibration arrays for channel 2 into the analyzer in FORM4 only. Values should be entered as 100 × power meter reading in dB.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>INPURAW1</td>
<td>Inputs raw data array 1 (&lt;i&gt;S&lt;/i&gt;&lt;sub&gt;11&lt;/sub&gt; data). After the data is received, the analyzer stops sweeping, error-corrects the data, then formats and displays the data.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>INPURAW2</td>
<td>Inputs raw data array 2 (&lt;i&gt;S&lt;/i&gt;&lt;sub&gt;21&lt;/sub&gt; data). After the data is received, the analyzer stops sweeping, error-corrects the data, then formats and displays the data.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>
INPURAW3 Inputs raw data array 3 ($S_{12}$ data). After the data is received, the analyzer stops sweeping, error-corrects the data, then formats and displays the data.

INPURAW4 Inputs raw data array 4 ($S_{22}$ data). After the data is received, the analyzer stops sweeping, error-corrects the data, then formats and displays the data.

1. These commands input an individual error coefficient array. Before sending an array, issue a \texttt{CALI}XXX; command, where XXXX specifies the calibration type. (See “CALI” earlier in this book.) Then input the array or arrays. Lastly store the data with the \texttt{SAVC} command. The instrument goes into hold, displaying uncorrected data. Complete the process by triggering a sweep, with the \texttt{CONT} command (for continuous sweep) or the \texttt{SING} command (for a single sweep). See Table 1-4 for the contents of the different arrays.

2. Does not require a preceding \texttt{“FORM”} command.

<td></td>
</tr>
</tbody>
</table>

1. One path, 2-port cal duplicates arrays 1 to 6 in arrays 7 to 12.
2. Response and isolation corrects for crosstalk and transmission tracking in transmission measurements, and for directivity and reflection tracking in reflection measurements.
3. This term is used to generate the calibration coefficients, but is not used during measurement error correction.

**Meaning of first subscript:**
- D: directivity
- S: source match
- R: reflection tracking
- X: crosstalk or isolation
- L: load match
- T: transmission tracking

**Meaning of second subscript:**
- F: forward
- R: reverse

---

### Front Panel Equivalents

GPIB only: no front panel equivalent.
INSM

Syntax

INSM<EXSA|EXSM|NETA|TUNR>; or INSM<EXSA|EXSM|NETA|TUNR>?;

Description

These commands select the instrument mode.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

| KOR?    | Queries and outputs the last key code¹ or front panel knob count:  
  • If the reply is positive, it is a key code.  
  • If it is negative, then set bit 15 equal to bit 14, and the resulting two-byte integer is the front panel knob count. It can be either positive or negative. There are about 120 counts per turn. | N/A   | <num><LF> |

¹. See Figure 1-1 on page 1-113 for front panel key codes.

Front Panel Equivalents

GPIB only: no front panel equivalent.
LAB

Syntax

LAB<K|S><$>;

Description

These commands enter a string <$> as either a cal kit label, or a cal standard label.

</tbody>
</table>
**LIM**

**Syntax**

\[ \text{LIM}<D|L|M|S|U><\text{num}>[\text{DB}|\text{HZ}]; \]

**Description**

These commands edit a limit test segment. The limit table editing is begun with \( \text{EDITLIML}; \), and a segment is brought up for editing with \( \text{SEDI}<\text{num}>; \) or added using \( \text{SADD}; \). The segment is closed with \( \text{SDON;} \), the table is closed with \( \text{EDITDONE}; \).

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIMD</td>
<td>Sets the limit delta value while editing a limit line segment.</td>

</tr>
<tr>
<td>LIMU</td>
<td>Sets the upper limit value.</td>
<td>amplitude range(^1)</td>
<td>see “Note” below</td>
</tr>
</tbody>
</table>

1. For log mag: ± 500 dB. For phase: ± 500 degrees. For Smith chart and Polar: ± 500 units. For linear magnitude: ± 500 units. For SWR: ± 500 units. The scale is always positive, and has minimum values of 0.001 dB, 10\(^{-12}\) degrees, 10\(^{-15}\) seconds, and 10 picounits.
2. For frequency or power sweeps, refer to “Preset State and Memory Allocation,” in your analyzer’s reference guide. For CW time: 0 to 24 hours. For frequency sweep, transform on: ± 1/frequency step. For CW time sweep, transform on: ± 1/time step.

**NOTE**

Currently these commands can be queried by sending the command followed by the \texttt{OUTPACTI} command, as in the following example to query the upper limit value:

\[ 10 \text{ OUTPUT } 716; "\text{LIMU}; \text{OUTPACTI};" \]

Future revisions of firmware may support the standard query form (which currently always returns a zero) for these commands.

<td>amplitude range&lt;sup&gt;3&lt;/sup&gt;</td>
<td>&lt;num&gt;&lt;L_F&gt;</td>
</tr>
<tr>
<td>MARKMAXI</td>
<td>Same as SEAMAX (search for maximum on current channel's trace).</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>MARKMIDD</td>
<td>Makes the marker amplitude the limit segment middle value during a limit</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>segment edit.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MARKMINI</td>
<td>Same as SEAMIN (search for minimum on current channel's trace).</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>MARKOFF</td>
<td>Turns all markers and marker functions off.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>MARKREF</td>
<td>Sets the reference value to that of the active marker's amplitude.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>MARKSPAN</td>
<td>Sets the span for the entire trace to that of the span between the active</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>marker and the delta reference marker.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MARKSTAR</td>
<td>Sets the start stimulus to that of the active marker's.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>MARKSTIM</td>
<td>During a limit segment edit, sets the limit stimulus break point to that</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>of the active marker's.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MARKSTOP</td>
<td>Sets the stop stimulus to that of the active marker's.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>MARKUNCO</td>
<td>Uncouples the markers between channels, as opposed to MARKCOUP.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>MARKZERO</td>
<td>Places the fixed marker at the active marker position and makes it the delta</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>reference.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. For frequency or power sweeps, refer to “Preset State and Memory Allocation,” in your analyzer’s reference guide. For CW time: 0 to 24 hours. For frequency sweep, transform on: ±1/frequency step. For CW time sweep, transform on: ±1/time step.
2. For example, on a 201 point sweep, <num> can range from 0 to 200.
3. For log mag: ±500 dB. For phase: ±500 degrees. For Smith chart and Polar: ±500 units.
   For linear magnitude ±500 units. For SWR: ±500 units. The scale is always positive, and has minimum values of 0.001dB, 10e-12 degrees, 10e-15 seconds, and 10 picounits.

Because this chapter is an “Alphabetical Command Reference,” the output commands have been listed alphabetically, rather than by function, in both the “Syntax” section and the “Description” section. Therefore, commands grouped together in the “Syntax” section are grouped alphabetically and/or due to common syntax form, not necessarily due to common functionality.

**Syntax**

```
OUTP<ACTI|AMAX|AMIN|APER>;
OUTP<CALC|ICAL><num>;
OUTP<CALK|CHAN|DATA|DATF|DATP|DATR|ERRO|FAIP|FORF|FORM>;
OUTPFARPLPT;
OUTP<IDEN|KEY|LEAS>;
OUTP<IPMCL|PMCAL><num>;
OUTP<MARK|MEMO|MEMF|MSTA|MWID|MWIL|OPTS|PLOT>;
OUTPLIM<num>;
OUTPLIM<F|L|M>;
OUTP<pre|Raf|RAW><num>;
OUTP<PRIN|PRNALL>;
OUTP<RFFR|SEGAF|SEGAM|SEGF|SEGM>;
OUTPRPLBNDALL;
OUTPRPLBNDPF;
OUTPRPLBNDVAL;
OUTPSEQ<num>;
OUTP<SERN|STAT|TITL>;
```

**Description**

Most commands that output an array require that you set the format for data transfers with the `FORM` command.

Many of these commands have an associated `INPUT` command that is used to transfer data to the analyzer. See “Symbol Conventions” on page 1-2 for a list of input commands.
<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>OUTPACTI</td>
<td>Outputs the value of the active function, or the last active function</td>
<td>N/A</td>
<td>$&lt;&gt;&lt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td></td>
<td>if the active entry area is off. The value is returned in ASCII format.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>OUTPAMAX(^1)</td>
<td>Outputs the max values for all limit line segments. This is an ASCII transfer (FORM4).</td>
<td>N/A</td>
<td>$&lt;\text{array}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPAMIN(^1)</td>
<td>Outputs the min values for all limit line segments. This is an ASCII transfer (FORM4).</td>
<td>N/A</td>
<td>$&lt;\text{array}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPAPER</td>
<td>Outputs the smoothing aperture in stimulus units, rather than as a percentage.</td>
<td>N/A</td>
<td>$&lt;\text{num}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPCALC</td>
<td>Outputs the selected error coefficient array for the active cal on the active channel.(^2)</td>
<td>two-digit integers 01–12</td>
<td>$&lt;\text{array}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPCALK</td>
<td>Outputs the currently active calibration kit, as a string of less than 1000 bytes. The data is in FORM1.</td>
<td>N/A</td>
<td>$&lt;&gt;&lt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPFARPLPT</td>
<td>Outputs the onscreen failed ripple point information in the following comma-separated value format: the number of failed points followed by pairs of numbers representing the first failed frequency, first failure value, second failed frequency, second failure value, and so on.</td>
<td>N/A</td>
<td>$&lt;\text{num, array}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPCHAN</td>
<td>Outputs the active channel number: 1, 2, 3, or 4.</td>
<td>N/A</td>
<td>$&lt;\text{num}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPDATA</td>
<td>Outputs the error-corrected data from the active channel in real/imaginary pairs. See Figure 5-1 on page 5-3.</td>
<td>N/A</td>
<td>$&lt;\text{array}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPDATF</td>
<td>Fast data transfer command for OUTPDATA.(^3)</td>
<td>N/A</td>
<td>$&lt;\text{array}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPDATP</td>
<td>Outputs the trace data indexed by point (see “SELPT”).</td>
<td>N/A</td>
<td>$&lt;\text{num, num}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPDATR</td>
<td>Outputs the trace data for a range of points (see “SELMINPT,” “SELMAXPT”). This is an ASCII (FORM4) transfer.</td>
<td>N/A</td>
<td>$&lt;\text{array}&gt;^{l}_{f}&gt;$</td>
</tr>
<tr>
<td>OUTPERRO</td>
<td>Outputs the oldest error message in the error queue. Sends the error number first, and then the error message itself, as an ASCII (FORM4) string no longer than 50 characters.</td>
<td>N/A</td>
<td>$&lt;\text{num, $}&gt;^{l}_{f}&gt;$</td>
</tr>

</tr>
</tbody>
</table>
| OUTPFAIP     | This command is similar to OUTPLIMF except that it reports the number of failures first, followed by the stimulus and trace values for each failed point in the test. ASCII format.  
1                                                                                         | N/A       | <array><IF>|
| OUTPFORF     | Fast data transfer command for OUTPFORM. Only the first number of the OUTPFORM data pair is transferred, unless the current format is polar or Smith chart; in those cases, both numbers (real and imaginary) are transferred.  
3 See also Table 1-6 on page 1-161.                                                         | N/A       | <array><IF>|
| OUTPFORM     | Outputs the formatted display data array from the active channel, in current display units. See Table 1-6 on page 1-161.                                                                                     | N/A       | <array><IF>|
| OUTPICAL     | Outputs the selected interpolated error coefficient array for the active cal on the active channel.                                                                                                        | two-digit integers 01–12 | <array><IF>|
| OUTPIDEN     | Outputs the identification string for the analyzer in the form: HEWLETT PACKARD, 87NNEX, xxxxxxxxxx, X.XX where 87NNEX is the model number of the instrument, xxxxxxxxxx is the serial number of the instrument, and X.XX is the firmware revision of the instrument.  
(Same as the “IDN?” command.)  
2                                                                                         | N/A       | <$><IF>    |
| OUTPIPMCL    | Outputs the interpolated power meter calibration array for channel 1 or channel 2. Values are returned as 100 times the interpolated power meter reading in dB.  
This is an ASCII transfer (FORM4).                                                          | integers 1 or 2 | <array><IF>|
| OUTPKEY      | Outputs the key code of the last key pressed in ASCII format. An invalid key is reported with a 63, a knob turn with a −1. See Figure 1-1 on page 1-113 for the front-panel key codes. | N/A       | <num><IF>  |
| OUTPLEAS     | Outputs the learn string, which contains the entire front panel state, the limit table, and the list frequency table. It is always in binary format not intended for decoding.                                                                 | N/A       | <learnstring><IF>|
| OUTPLIM      | Outputs the status of the limit test for the channel selected with <num>.  
1,4                                                                                         | integers 1–4 | <0|1|1><IF>|
| OUTPLIMF     | Outputs the limit test results for each failed point, followed by the number of failed points. This is an ASCII transfer.  
1,5                                                                                         | N/A       | <array><IF>|

</tr>
</thead>
<tbody>
<tr>
<td>OUTPLIML</td>
<td>Outputs the limit test results for each point in the sweep. This is an ASCII transfer.</td>
<td>N/A</td>
<td><code>&lt;array&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPLIMM</td>
<td>Outputs the limit test results at the active marker.</td>
<td>N/A</td>
<td><code>&lt;num,num,num,num,num&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPMARK</td>
<td>Outputs the active marker values. The first two numbers are the marker response values, and the last is the stimulus value. See Table 1-6 on page 1-161 for the meaning of the response values as a function of display format.</td>
<td>N/A</td>
<td><code>&lt;num,num,num&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPMEMF</td>
<td>Fast data transfer command for OUTPMEMO.</td>
<td>N/A</td>
<td><code>&lt;array&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPMEMO</td>
<td>Outputs the memory trace from the active channel. The data is in real/imaginary pairs, and can be treated the same as data read with the OUTPDATA command. See Figure 5-1 on page 5-3.</td>
<td>N/A</td>
<td><code>&lt;array&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPMSTA</td>
<td>Outputs the marker statistics in ASCII format: mean, standard deviation, and peak-to-peak variation in that order. If statistics is not on, it is turned on to generate current values and turned off again. See also &quot;MEASTAT:&quot;</td>
<td>N/A</td>
<td><code>&lt;num,num,num&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPMWID</td>
<td>Outputs the marker bandwidths search results in ASCII format: bandwidth, center, and Q in that order. If widths is not on, it is turned on to generate current values and then turned off again.</td>
<td>N/A</td>
<td><code>&lt;num,num,num&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPMWIL</td>
<td>Outputs the marker bandwidths search results in ASCII format: bandwidth, center, Q, and loss in that order. If widths is not on, it is turned on to generate current values and turned off again.</td>
<td>N/A</td>
<td><code>&lt;num,num,num,num&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPOPTS</td>
<td>Outputs an ASCII string of the options installed in the analyzer.</td>
<td>N/A</td>
<td><code>&lt;$&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPPLOT</td>
<td>Outputs the HP-GL plot string in ASCII format to the GPIB port. Can be directed to a plotter, or read into the computer.</td>
<td>N/A</td>
<td><code>&lt;$&gt;</code>&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPPMCAL</td>
<td>Outputs the power meter calibration array for channel 1 or channel 2. A default array is used if a power meter calibration sweep, TACKCS, has not been performed. Values are returned as 100 times the power meter reading in dB. This is an ASCII transfer (FORM4).</td>
<td>integers 1 or 2</td>

<td></td>
</tr>
<tr>
<td></td>
<td>band, second band number (2), ripple value of second band, and so on.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>OUTPRPLBNDPF</td>
<td>Outputs the pass/fail status for selected frequency band (see “SELBND”)</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td></td>
<td>as “1” (band passes) or as “0” (band fails).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>OUTPRPLBNDVAL</td>
<td>Outputs the ripple value for selected frequency band (see “SELBND”).</td>
<td>N/A</td>
<td>&lt;num&gt;&lt;LF&gt;</td>
</tr>
<tr>
<td>OUTPSEGAF</td>
<td>Outputs the segment number and its limit test status for all active</td>
<td>N/A</td>
<td>&lt;array&gt;&lt;LF&gt;</td>
</tr>
<tr>
<td></td>
<td>segments. This is an ASCII transfer.1,4</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
<td>Range</td>
<td>Response</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------</td>
<td>--------------</td>
</tr>
<tr>
<td>OUTPSEGAM</td>
<td>Outputs the limit test min/max for all segments. Outputs the segment number, max stimulus, max value, min stimulus, min value for all active segments. This is an ASCII transfer. (^1,4)</td>
<td>N/A</td>
<td>&lt;array&gt;&lt;f&gt;</td>
</tr>
<tr>
<td>OUTPSEGF</td>
<td>Outputs the limit test status for a specified segment. See also “SELSEG.” (^1,4)</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
<tr>
<td>OUTPSEGM</td>
<td>Outputs limit test min/max for a specified segment. See also “SELSEG.” (^1)</td>
<td>N/A</td>
<td>&lt;num,num&gt;&lt;f&gt;</td>
</tr>
<tr>
<td>OUTPSEQ</td>
<td>Outputs the specified sequence listing to the GPIB port.</td>
<td>integers 1–6</td>
<td>$&lt;f&gt;</td>
</tr>
<tr>
<td>OUTPSERN</td>
<td>Outputs a string that contains the serial number of the analyzer.</td>
<td>N/A</td>
<td>$&lt;f&gt;</td>
</tr>
<tr>
<td>OUTPSTAT</td>
<td>Returns the status byte as an ASCII integer (0–255) that can be interpreted as the 8-bit status byte. Refer to “The Status Byte” on page 6-6 for more information about the status byte. This command is the same as “STB?.”</td>
<td>N/A</td>
<td>&lt;num&gt;&lt;f&gt;</td>
</tr>
<tr>
<td>OUTPTITL</td>
<td>Outputs the display title in ASCII format.</td>
<td>N/A</td>
<td>$&lt;f&gt;</td>
</tr>
</tbody>
</table>

1. Refer to “Limit Line and Data Point Special Functions” on page 7-126.
2. See Table 1-5 for the contents of the different arrays. Each array is output in the currently set form determined by the FORM command. The data is in real/imaginary pairs, with the same number of pairs as points in the sweep.
3. This is one of four fast-data-transfer commands. These commands circumvent the internal “byte handler” routine and output trace dumps as block data. In other words, the analyzer outputs the entire array without allowing any process swapping to occur. FORM4 (ASCII) data transfer times are not affected by these routines. However, there are speed improvements with binary data formats.
4. Values returned for limit test status are: 0 (fail), 1 (pass), or −1 (no limit).
5. This command outputs the limit test results. The results consist of four fields. First is the stimulus value for the point. Second is an integer indicating test status. Third is the upper limit at that point. Fourth is the lower limit at that point. If there are no limits at that point, the third and fourth fields are zero.
6. If there is not a currently active 2-port cal (full 2-port or TRL), this command will only output data for whichever measurement is currently selected on the active channel, regardless of which number (<1|2|3|4>) is appended to the command.
7. The I/O needs to be set to terminate upon two consecutive $<f>$s when using this command.
8. This command only applies to 8753ET/ES analyzers.
Front Panel Equivalents

GPIB only: no front panel equivalent.

1. One path, 2-port cal duplicates arrays 1 to 6 in arrays 7 to 12.
2. Response and isolation corrects for crosstalk and transmission tracking in transmission measurements, and for directivity and reflection tracking in reflection measurements.
3. This term is used to generate the calibration coefficients, but is not used during measurement error correction.

**Meaning of first subscript:**
- D: directivity
- S: source match
- R: reflection tracking
- X: crosstalk or isolation
- L: load match
- T: transmission tracking

**Meaning of second subscript:**
- F: forward
- R: reverse

<tr>
<td>POWT</td>
<td>Sets source power on or off. Works the opposite of the SOUP command. Sending POWTON turns source power off. Sending POWTOFF turns source power on.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

### Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>POWT</td>
<td>Power</td>
<td>POWER TRIP ON OFF</td>
</tr>
</tbody>
</table>

1. 8753ES Option 011 analyzers only.
### PRAN

**Syntax**

PRAN<num>;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRAN</td>
<td>Sets the source power range. See also &quot;POWR.&quot;</td>
<td>integers¹ 0–7 integers² 01–12</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. Use single-digit integers 0 through 7 for 8753ET/ES analyzers. PRAN0 through PRAN7 are used for ranges 0 through 7.
2. Use two-digit integers 01 through 12 for 8720E series analyzers. PRAN01 through PRAN12 are used for ranges 0 through 11.

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRAN</td>
<td>Power</td>
<td>RANGE n</td>
</tr>
</tbody>
</table>

### PREP

**Syntax**

PREP;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREP</td>
<td>Displays the previous page of the operating parameters list. (Use OPEP to display the operating parameters list.)</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>PREP</td>
<td>Copy</td>
<td>PREVIOUS PAGE</td>
</tr>
</tbody>
</table>
PRES

Syntax

PRES;

Description

PRES

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRES</td>
<td>Presets the analyzer to the factory preset state. OPC-compatible. See also Appendix A, “Preset Conditions.”</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRES</td>
<td>Preset</td>
<td>N/A</td>
</tr>
</tbody>
</table>

NOTE

Pressing the (Preset) key on the analyzer will either invoke the factory preset state, or a user-selected state (if one has been set up). Sending the PRES command will always invoke the factory preset state. This is true even if the analyzer is currently set up to recall a user preset state when the (Preset) key is pressed. For more information on user presets, see your analyzer’s user’s guide.

NOTE

This command should use OPC? to prevent timing errors with subsequent commands. Example code written in BASIC:

```
10 OUTPUT 716;"OPC?;PRES;"
20 ENTER 716;X
```
PRI

**Syntax**

PRI<C|S>; or PRI<C|S>?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>

</tbody>
</table>
RAWOFFS

Syntax

RAWOFFS<ON|OFF>; or RAWOFFS?;

Description

By turning raw offsets off (RAWOFFSOFF), a full two-port error correction can be performed without including the effects of the offsets. It also saves substantial time at recalls and during frequency changes (see SM8). Raw offsets follow the channel coupling. RAWOFFS and SAMC are linked in that when one changes state, so does the other. See “Example 2G: Take4 — Error Correction Processed on an External PC” on page 7-48.

<td>System</td>
<td>RETRACE PWR</td>
</tr>
</tbody>
</table>
**REV**

**Syntax**

\[ \text{REV} \langle I | M | T \rangle ; \]

**NOTE**

These commands only apply to ES models.

**Description**

These commands are OPC-compatible if there is only one standard in the class. If there is just one standard, that standard is measured automatically. If there is more than one standard in the class, the class command only calls another menu.

<table>
<thead>
<tr>

RF

Syntax

```plaintext
RF<GTLO|LTLO>;
```

Description

These 2 commands are used in frequency offset mode measurements.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RF_GTLO</td>
<td>Sets RF greater than LO.</td>
<td>N/A</td>

</tbody>
</table>
RFLP

Syntax

RFLP; or RFLP?;

NOTE This command only applies to ET models.

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFLP¹</td>
<td>Sets the measurement mode to “Reflection.” (See also “S11.”)</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

¹ This command can also be used on ES models to set the measurement mode to “Refl:FWD S11.”

Front Panel Equivalents

<table>
<thead>
<tr>

</table>
### RLIMM

**Syntax**

RLIMM<num>[DB]; or RLIMM?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMM</td>
<td>Sets the value of the maximum allowable ripple limit for current frequency band.</td>
<td>0.01 to 100 dB</td>
<td>&lt;num&gt;&lt;F&gt;</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMM</td>
<td>System</td>
<td>MAXIMUM RIPPLE</td>
</tr>
</tbody>
</table>

### RLIMSTP

**Syntax**

RLIMSTP<num>[HZ|KHZ|MHZ|GHZ]; or RLIMSTP?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMSTP</td>
<td>Sets the stop frequency of the current frequency band.</td>
<td>stimulus range¹</td>
<td>&lt;num&gt;&lt;F&gt;</td>
</tr>
</tbody>
</table>

1. Refer to “Preset State and Memory Allocation” in your analyzer’s reference guide.

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMSTP</td>
<td>System</td>
<td>MAXIMUM FREQUENCY</td>
</tr>
</tbody>
</table>
**RLIMSTR**

**Syntax**

RLIMSTR<num>[HZ|KHZ|MHZ|GHZ]; or RLIMSTR?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMSTR</td>
<td>Sets the start frequency of the current ripple limit.</td>
<td>stimulus range(^1)</td>
<td>&lt;num&gt;[&lt;LF&gt;]</td>
</tr>
</tbody>
</table>

\(^1\) Refer to “Preset State and Memory Allocation” in your analyzer’s reference guide.

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMSTR</td>
<td>System</td>
<td>MINIMUM FREQUENCY</td>
</tr>
</tbody>
</table>

---

**RLIMTEST**

**Syntax**

RLIMTEST<ON|OFF>; or RLIMTEST?;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMTEST</td>
<td>Turns the ripple limit test on and off.</td>
<td>N/A</td>
<td>&lt;0</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMTEST</td>
<td>System</td>
<td>RIPL TEST on OFF</td>
</tr>
</tbody>
</table>
**RLIMVAL**

**Syntax**

RLIMVAL<OFF|ABS|MAR>;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMVAL</td>
<td>Displays the ripple limit value of the selected band (see “SELBND”) in absolute format (ABS) or margin format (MAR). OFF turns the displayed ripple limit value off.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>RLIMVAL</td>
<td>System</td>
<td>RIPL VALUE []</td>
</tr>
</tbody>
</table>

**RSCO**

**Syntax**

RSCO;

**Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSCO</td>
<td>Resets display colors to the factory default settings.</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Front Panel Equivalents**

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSCO</td>
<td>Display</td>
<td>RESET COLOR</td>
</tr>
</tbody>
</table>
RST

Syntax

RST;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>RST</td>
<td>Presets the analyzer to the factory preset state. OPC-compatible. See Appendix A, “Preset Conditions.”</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Front Panel Equivalents

<table>
<thead>
<tr>
<th>Command</th>
<th>Hardkey</th>
<th>Softkey</th>
</tr>
</thead>
<tbody>
<tr>
<td>RST</td>
<td>Preset</td>
<td>N/A</td>
</tr>
</tbody>
</table>

NOTE Pressing the (Preset) key on the analyzer will either invoke the factory preset state, or a user-selected state (if one has been set up). Sending the RST command will always invoke the factory preset state. This is true even if the analyzer is currently set up to recall a user preset state when the (Preset) key is pressed. For more information on user presets, see your analyzer's user's guide.
### S

#### Syntax

\[ S<11\mid12\mid21\mid22>; \text{ or } S<11\mid12\mid21\mid22>?; \]

#### Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>S11</td>
<td>Forward reflection measurement(^1) (See also “RFLP.”)</td>
<td>N/A</td>
<td>(&lt;0\mid1\times F&gt;)</td>
</tr>
<tr>
<td>S12</td>
<td>Reverse transmission measurement(^2)</td>
<td>N/A</td>
<td>(&lt;0\mid1\times F&gt;)</td>
</tr>
<tr>
<td>S21</td>
<td>Forward transmission measurement(^3) (See also “TRAP.”)</td>
<td>N/A</td>
<td>(&lt;0\mid1\times F&gt;)</td>
</tr>
<tr>
<td>S22</td>
<td>Reverse reflection measurement(^2)</td>
<td>N/A</td>
<td>(&lt;0\mid1\times F&gt;)</td>
</tr>
</tbody>
</table>

1. The S11 command can also be used on ET models to set the measurement mode to “Reflection.”
2. The S12 and S22 commands do not apply to ET models.
3. The S21 command can also be used on ET models to set the measurement mode to “Transmissn.”

SEG

Syntax
SEG<IFBW|POWER><num>;

Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>Range</th>
<th>Query Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGIFBW</td>
<td>Sets the IF BW for the active segment of a list-frequency table</td>
<td>Choose from 10, 30, 100, 300, 1000, 3000, 3700, 6000</td>
<td>see “Note” below</td>
</tr>
<tr>
<td>SEGPOWER</td>
<td>Sets the power for the active segment of a list-frequency table</td>
<td>output power range of your analyzer(^1)</td>
<td>see “Note below”</td>
</tr>
</tbody>
</table>

\(^1\) The output power range is dependent upon the model and option configuration of your analyzer. Refer to your analyzer’s reference guide to determine the output power range of your analyzer.

NOTE
Currently these commands can be queried by sending the command followed by the OUTPACTI command, as in the following example to query the upper limit value:

```
10 OUTPUT 716;"SEGIFBW;OUTPACTI;"
```

Future revisions of firmware may support the standard query form (which currently always returns a zero) for these commands.

Front Panel Equivalents

</tr>
</tbody>
</table>

Front Panel Equivalents

GPIB only: no front panel equivalent.
TSTIO

Syntax

TSTIO<FWD|REV><num>; or TSTIO<FWD|REV>?

Description

Both of these commands define 3 bits, D0 through D2, on the test set connector I/O. Be careful that you do not also set a value to ATTP1 and ATTP2 as there is interaction between these commands and they will change the values you have set for D0 through D2 and will couple the channels together. Values for ATTP1 and ATTP2 translate to the following values for D0 through D2:

<table>
<thead>
<tr>
<th>ATTP1/ATTP2</th>
<th>D0-D2</th>
</tr>
</thead>
<tbody>
<tr>

2 Introduction to Instrument Control
Using This Chapter

This chapter is an introduction to the remote operation of your analyzer using an external controller. The chapter is divided into two main sections:

- “Instrument Control using the VXI plug&play Driver” on page 2-3
- “Instrument Control using HP BASIC” on page 2-9

You should be familiar with the operation of the analyzer before attempting to remotely control the analyzer via the General Purpose Interface Bus (GPIB). See your analyzer’s user’s guide and reference guide for operating information.

This manual is not intended to teach programming or to discuss GPIB theory except at an introductory level.

Programming examples that demonstrate the remote operation of the analyzer are documented in Chapter 7, “Programming Examples,” and are also provided on the CD-ROM that was shipped with this manual. All example programs are provided in HP BASIC, and most are also provided in Visual C++ and Visual BASIC for use with the VXI plug&play driver.
Instrument Control using the VXIplug&play Driver

VXIplug&play is a term indicating conformance to a set of system-level standards produced by the VXIplug&play Systems Alliance. The charter of the alliance was “to improve the effectiveness of VXI-based solutions by increasing ease-of-use and improving the interoperability of multi-vendor VXI systems.”

Installing the VXIplug&play driver on your computer will allow you to control the analyzer via common programming environments without having to learn the instrument-specific mnemonics.

Requirements

The VXIplug&play driver for your analyzer is designed for a PC operating Windows 95 or Windows NT version 3.51 or higher. The driver requires a virtual instrument software architecture (VISA)-compatible GPIB interface, and the VISA I/O Library version 1.1 or higher. The driver is compatible with the following programming environments:

- Microsoft Visual Basic, version 4.0 or higher
- Microsoft Visual C++, version 4.0 or higher
- Borland C++, version 4.5 or higher
- HP VEE, version 3.2 or higher
- National Instruments LabWindows/CVI, version 4.0.1 or higher
- National Instruments LabVIEW, version 4.0.1 or higher

Installing the VXIplug&play Driver

NOTE This procedure assumes that you have installed a VISA-compatible GPIB interface and the VISA I/O library, version 1.1 or higher. It also assumes that you have installed—and are familiar with—one of the programming environments listed above.

1. The install program for the VXIplug&play driver for your analyzer is located in the root directory of the CD-ROM that accompanied this manual. The file is titled “875x.exe”

   a. If you need to order a new CD-ROM, contact Agilent Technologies and order part number 08753-10039.

   b. You can also download the file from the Web. Go to http://www.tm.agilent.com and follow the “Software and Driver” and “Instrument Driver” links.

2. Run “875x.exe” to install the VXIplug&play driver on your computer. The default directory that is used by the install-shield is vxipnp\winxx\hp875x, where winxx designates the operating system in use by your computer, such as winnt, win95, etc.

3. If you have difficulty installing the VXIplug&play driver, contact Agilent Technologies by calling the nearest sales or service office. Refer to “Agilent Technologies Sales and Service Offices” on page iv for a list of contacts.
System Setup

1. Use an GPIB interconnect cable (such as 10833A/B/C/D) to connect the analyzer to the GPIB interface card on your computer.

2. Switch on the computer.

3. Switch on the analyzer.

   a. To verify the analyzer’s address, press:

   ![Set Addresses](Local SET ADDRESSES ADDRESS: 87xx)

      The analyzer has only one GPIB interface, though it occupies two addresses: one for the instrument and one for the display. The display address is equal to the instrument address with the least-significant bit incremented. The display address is automatically set each time the instrument address is set.

      The default analyzer addresses are:

      — 16 for the instrument
      — 17 for the display

   ![CAUTION](Other devices connected to the bus cannot occupy the same address as the analyzer or the display)

      The analyzer should now be displaying the instrument's address in the upper right section of the display. If the address is not 16, return the address to its default setting (16) by pressing:

      ![Set Address](16 x1 Preset)

   b. Set the system control mode to either “pass-control” or “talker/listener” mode. These are the only control modes in which the analyzer will accept commands over GPIB. For more information on control modes, see “Bus Device Modes” on page 3-12. To set the system-control mode, press:

      ![Talker/Listener](Local TALKER/LISTENER)

      or

      ![Use Pass Control](Local USE PASS CONTROL)
Verifying the Bus Connection

Check the interface bus connection and operation by following the appropriate procedure (for the type of interface card you are using) below.

Interface Bus Verification Procedure (GPIB Interface Card)

1. Check the bus connection by running the VISA Assistant in the I/O Libraries. The VISA Assistant will automatically report what it finds on the bus. Refer to Figure 2-1. Notice that the VISA Assistant is reporting instruments at addresses 16 and 17. As mentioned earlier, these addresses designate the instrument and its display, respectively.

![Figure 2-1 VISA Assistant Window](image)

2. To further verify GPIB operation, send a preset command to the analyzer by doing the following in the VISA Assistant window (refer to Figure 2-1):

   a. Single-click on “GPIB0::16::INSTR” to highlight it.
   b. Make sure that the “Formatted I/O” tab is selected.
   c. Enter `PRES;` in the text box.
   d. Click on “viPrintf.”
   e. This command should preset the analyzer. If an instrument preset does not occur, there is a problem. Check all GPIB address settings and physical connections. Most GPIB problems are caused by an incorrect address or faulty/loose GPIB cables.
Interface Bus Verification Procedure (National Instruments Card)

1. Check the bus connection by running Win32 VISA Interactive Control. When this program is run, it automatically reports what it finds on the bus. Refer to Figure 2-2. Notice that the program is reporting instruments at addresses 16 and 17. As mentioned earlier, these addresses designate the instrument and its display, respectively.

Figure 2-2 Win32 VISA Interactive Control Window: Bus Report

2. To further verify GPIB operation, double click on “GPIB0::16::INSTR” and then perform the following steps. Refer to Figure 2-3 for a view of the window you will be using.
   a. Make sure that the “Basic I/O” tab is selected.
   b. Click on the “Write” tab.
   c. Enter \texttt{PRES;} in the “Buffer” text box.
   d. Click on “Execute.”
   e. This command should preset the analyzer. If an instrument preset does not occur, there is a problem. Check all GPIB address settings and physical connections. Most GPIB problems are caused by an incorrect address or faulty/loose GPIB cables.
Controlling the Analyzer with the VXIplug&play Driver

The “Programming Examples” CD-ROM that was shipped with this manual includes many example programs that can be used to control your analyzer. Example programs written for Visual C++ are located in the “vc” directory on the CD-ROM, and example programs written for Visual BASIC are located in the “vb” directory. These examples are also available within the Windows help file for the VXI plug&play driver. The following sections provide some information on using the VXIplug&play driver with the Visual C++ and Visual BASIC programming environments. Refer to Chapter 7, “Programming Examples,” for detailed information on each of the example programs.

Using Visual BASIC to Control the Analyzer

When using Visual BASIC, you will need to include the two files listed below in your project. They were installed on your computer in the following directories when you installed the driver:

- \vxipnp\winxx\hp875x\hp875x.bas
- \vxipnp\winxx\include\visa32.bas

**NOTE**

The directories shown above are the default locations for these files. (“winxx” indicates the operating system you are using, such as winnt, win95, etc.) If you designated a different path during installation, you will need to amend the path above to include the specific path that you indicated during installation.
Using Visual C++ to Control the Analyzer

When using Visual C++, you will need to include the file listed below in your project. The file was installed on your computer in the following directory when you installed the driver:

\vxi\win\lib\msi\hp875x_32.lib

**NOTE**

The directory shown above is the default location for this file. ("winxx" indicates the operating system you are using, such as winnt, win95, etc.) If you designated a different path during installation, you will need to amend the path above to include the specific path that you indicated during installation.
Instrument Control using HP BASIC

This section describes how to control the analyzer using HP BASIC 6.2 (or higher), or HP BASIC for Windows 6.3 (or higher) on one of the following computers:

- HP 9000 Series 200/300
- HP 9000 Series 700 with HP BASIC-UX
- PC with a GPIB interface card installed

For more information on HP BASIC, see Table 2-1. For more information concerning the General Purpose Interface Bus, see Table 2-2.

Required Equipment

- Computer running HP BASIC 6.2 (or higher) or HP BASIC for Windows 6.3 (or higher)
- Supported GPIB interface card
- GPIB interconnect cables (such as 10833A/B/C/D)
System Setup and GPIB Verification

1. Connect the analyzer to the computer with an GPIB cable as shown in Figure 2-4.
2. Switch on the computer, and launch HP BASIC or HP BASIC for Windows.
3. Switch on the analyzer.
   a. To verify the analyzer’s address, press:

   **Local** SET ADDRESSES ADDRESS: 87xx

   The analyzer has only one GPIB interface, though it occupies two addresses: one for the instrument and one for the display. The display address is equal to the instrument address with the least-significant bit incremented. The display address is automatically set each time the instrument address is set.

   The default analyzer addresses are:
   — 16 for the instrument
   — 17 for the display

---

**CAUTION** Other devices connected to the bus cannot occupy the same address as the analyzer.

The analyzer displays the instrument’s address in the upper right section of the display. If the address is not 16, return the address to its default setting (16) by pressing:

16 x1 Preset
b. Set the system control mode to either “pass-control” or “talker/listener” mode. These are the only control modes in which the analyzer will accept commands over GPIB. For more information on control modes, see “Bus Device Modes” on page 3-12. To set the system-control mode, press:

- [Local] TALKER/LISTENER
- or

- [Local] USE PASS CONTROL

4. Check the interface bus by performing a simple command from the computer controller. Type the following command on the controller:

```
OUTPUT 716;"PRES;" [Exec] or [Return]
```

---

**NOTE**

HP 9000 Series 300 computers use the [Return] key as both execute and enter. Some other computers may have an [Enter], [Exec], or [Exec] key that performs the same function. For reasons of simplicity, the notation [Return] is used throughout this document.

This command should preset the analyzer. If an instrument preset does not occur, there is a problem. Check all GPIB addresses and connections. Most GPIB problems are caused by an incorrect address or faulty/loose GPIB cables.
Sending Commands

A remote controller can manipulate the functions of the analyzer by sending commands to the analyzer via the General Purpose Interface Bus (GPIB). The commands used are specific to the analyzer. Remote commands executed over the bus take precedence over manual commands executed from the instrument’s front panel. Remote commands are executed as soon as they are received by the analyzer. A command only applies to the active channel (except in cases where functions are coupled between channels). Most commands are equivalent to front-panel hardkeys and softkeys.

Command Structure in BASIC

Consider the following BASIC command for setting the analyzer’s start frequency to 50 MHz:

```
OUTPUT 716;"STAR 50 MHZ;"
```

The command structure in BASIC has several different elements:

- **the BASIC command statement**: `OUTPUT` - The BASIC data-output statement.
- **the appendage**: `716` - The data is directed to interface 7 (GPIB), and on to the device at address 16 (the analyzer). This appendage is terminated with a semicolon. The next appendage is `STAR`, the instrument mnemonic for setting the analyzer’s start frequency.
- **data**: `50` - a single operand used by the root mnemonic `STAR` to set the value.
- **unit**: `MHZ` - the units that the operand is expressed in.
- **terminator**: `;` - indicates the end of a command, enters the data, and deactivates the active-entry area.

The “`STAR 50 MHZ;`” command performs the same function as pressing the following keys on the analyzer’s front panel:

```
Start 50 M/µ
```

`STAR` is the root mnemonic for the start key, 50 is the data, and `MHZ` are the units. Where possible, the analyzer’s root mnemonics are derived from the equivalent key label. Otherwise they are derived from the common name for the function. Chapter 1, “Alphabetical Command Reference,” lists all the root mnemonics and all the different units accepted.

The semicolon (;) following `MHZ` terminates the command within the analyzer. It removes start frequency from the active-entry area, and prepares the analyzer for the next command. If there is a syntax error in a command, the analyzer will ignore the command and look for the next terminator. When it finds the next terminator, it starts processing incoming commands normally. Characters between the syntax error and the next terminator are lost. A line feed also acts as a terminator. The BASIC `OUTPUT` statement transmits a carriage return/line feed following the data. This can be suppressed by putting a semicolon at the end of the statement.
The `OUTPUT 716;` statement will transmit all items listed (as long as they are separated by commas or semicolons) including:

- literal information enclosed in quotes,
- numeric variables,
- string variables,
- and arrays.

A carriage return/line feed is transmitted after each item. Again, this can be suppressed by terminating the commands with a semicolon. The analyzer automatically goes into remote mode when it receives an OUTPUT command from the controller. When this happens, the front-panel remote (R) and listen (L) GPIB status indicators illuminate. In remote mode, the analyzer ignores any data that is input with the front-panel keys, with the exception of `LOCAL`. Pressing `LOCAL` returns the analyzer to manual operation, unless the universal GPIB command `LOCAL LOCKOUT` has been issued. There are two ways to exit from a local lockout. Either issue the `LOCAL` command from the controller or cycle the line power on the analyzer.

Setting a parameter such as start frequency is just one form of command the analyzer will accept. It will also accept simple commands that require no operand at all. For example, execute:

```
OUTPUT 716;"AUTO;"
```

In response, the analyzer autoscales the active channel. Autoscale only applies to the active channel, unlike start frequency, which applies to both channels as long as the channels are stimulus-coupled.

The analyzer will also accept commands that switch various functions on and off. For example, to switch on dual-channel display, execute:

```
OUTPUT 716;"DUACON;"
```

`DUACON` is the analyzer root mnemonic for “dual-channel display on.” This causes the analyzer to display both channels. To go back to single-channel display mode, for example, switching off dual-channel display, execute:

```
OUTPUT 716;"DUACOFF;"
```

The construction of the command starts with the root mnemonic `DUAC` (dual-channel display) and `ON` or `OFF` is appended to the root to form the entire command.

The analyzer does not distinguish between upper- and lower-case letters. For example, execute:

```
OUTPUT 716;"auto;"
```

---

**NOTE** The analyzer also has a debug mode to aid in troubleshooting systems. When the debug mode is ON, the analyzer scrolls incoming GPIB commands across the display. To manually activate the debug mode, press `GPIB DIAG ON`. To deactivate the debug mode from the controller, execute:

```
OUTPUT 716;"DEBUOFF;"
```
Command Query
Suppose the operator has changed the power level from the front panel. The computer can find the new power level using the analyzer’s command-query function. If a question mark is appended to the root of a command, the analyzer will output the value of that function.

For instance, `POWE 7 DB;` sets the analyzer’s output power to 7 dB, and `POWE?;` outputs the current RF output power at the test port to the system controller. For example:

Type `SCRATCH` and press `Return` to clear old programs.

Type `EDIT` and press `Return` to access the edit mode. Then type in:

```
10 OUTPUT 716;"POWE?;"
20 ENTER 716;Reply
30 DISP Reply
40 END
```

| NOTE | Most commands can also be queried by sending the command (without a value) and then sending the `OUTPACTI` command, as in the following example that queries the power value:

```
10 OUTPUT 716;"POWE;OUTPACTI;"
```

Running the Program  The computer will display the preset source-power level in dBm. Change the power level by pressing `Local Power` x1. Now run the program again.

When the analyzer receives `POWE?;`, it prepares to transmit the current RF source-power level. The BASIC statement `ENTER 716` allows the analyzer to transmit information to the computer by addressing the analyzer to talk. This illuminates the analyzer front-panel talk (T) light. The computer places the data transmitted by the analyzer into the variables listed in the `ENTER` statement. In this case, the analyzer transmits the output power, which gets placed in the variable `Reply`.

The `ENTER` statement takes the stream of binary-data output from the analyzer and reformats it back into numbers and ASCII strings. With the formatting set to its default state, the `ENTER` statement will format the data into real variables, integers, or ASCII strings, depending on the variable being filled. The variable list must match the data the analyzer has to transmit. If there are not enough variables, data is lost. If there are too many variables for the data available, a BASIC error is generated.

The formatting done by the `ENTER` statement can be changed. For more information on data formatting, see “Array-Data Formats” on page 4-6. The formatting can be deactivated to allow binary transfers of data. Also, the `ENTER USING` statement can be used to selectively control the formatting.
ON/OFF commands can be also be queried. The reply is a one (1) if the function is active, a zero (0) if it is not active. Similarly, if a command controls a function that is underlined on the analyzer softkey menu when active, querying that command yields a one (1) if the command is underlined, a zero (0) if it is not. For example, press [Meas]. Though there are seven options on the measurement menu, only one is underlined at a time. The underlined option will return a one (1) when queried.

For instance, rewrite line 10 as:

```
10 OUTPUT 716;"DUAC??;"
```

Run the program once and note the result. Then press [Local] [Display] [DUAL CHAN] to toggle the display mode, and run the program again.

Another example is to rewrite line 10 as:

```
10 OUTPUT 716;"PHAS??;"
```

In this case, the program will display a one (1) if phase is currently being displayed. Since the command only applies to the active channel, the response to the PHAS? inquiry depends on which channel is active.

**Operation Complete**

Occasionally, there is a need to query the analyzer as to when certain analyzer operations have completed. For instance, a program should not have the operator connect the next calibration standard while the analyzer is still measuring the current one. To provide such information, the analyzer has an “operation complete” reporting mechanism, or OPC command, that will indicate when certain key commands have completed operation. The mechanism is activated by sending either OPC or OPC? immediately before an OPC-compatible command. When the command completes execution, bit 0 of the event-status register will be set. If OPC was queried with OPC?, the analyzer will also output a one (1) when the command completes execution.

As an example, type [SCRATCH] and press [Return].

Type [EDIT] and press [Return].

Type in the following program:

```
10 OUTPUT 716;"SWET 3 S;OPC?;SING;"
```

Set the sweep time to 3 seconds, and OPC a single sweep.

```
20 DISP "Sweeping"
```

The program will halt at this point until the analyzer completes the sweep and issues a one (1).

```
30 ENTER 716;Reply
```

```
40 DISP "Done"
```

```
50 END
```

---

Chapter 2 2-15
Running the Program  Running this program causes the computer to display the sweeping message as the instrument executes the sweep. The computer will display `DONE` just as the instrument goes into hold. When `DONE` appears, the program could then continue on, being assured that there is a valid data trace in the instrument.

Preparing for Remote (GPIB) Control

At the beginning of a program, the analyzer is taken from an unknown state and brought under remote control. This is done with an abort/clear sequence. `ABORT 7` is used to halt bus activity and return control to the computer. `CLEAR 716` will then prepare the analyzer to receive commands by:

- clearing syntax errors
- clearing the input-command buffer
- clearing any messages waiting to be output

The abort/clear sequence readies the analyzer to receive GPIB commands. The next step involves programming a known state into the analyzer. The most convenient way to do this is to preset the analyzer by sending the `PRES` (preset) command. If preset cannot be used, the status-reporting mechanism may be employed. When using the status-reporting register, `CLES` (Clear Status) can be transmitted to the analyzer to clear all of the status-reporting registers and their enables.

Type `SCRATCH` and press `Return`. Type `EDIT` and press `Return`. Type in the following program:

10 ABORT 7  This halts all bus action and gives active control to the computer.

20 CLEAR 716  This clears all GPIB errors, resets the GPIB interface, and clears the syntax errors. It does not affect the status-reporting system.

30 OUTPUT 716;"PRES;"  Presets the instrument. This clears the status-reporting system, as well as resets all of the front-panel settings, except for the GPIB mode and the GPIB addresses.

40 END  Running this program brings the analyzer to a known state, ready to respond to GPIB control.

The analyzer will not respond to GPIB commands unless the remote line is asserted. When the remote line is asserted, the analyzer is addressed to listen for commands from the controller. In remote mode, all the front-panel keys are disabled (with the exception of `Local` and the line-power switch). `ABORT 7` asserts the remote line, which remains asserted until a `LOCAL 7` statement is executed.

Another way to assert the remote line is to execute:

REMOTE 716

This statement asserts the analyzer’s remote-operation mode and addresses the analyzer to listen for commands from the controller. Press any front-panel key except `Local`. Note that none of the front-panel keys will respond until `Local` has been pressed.
Local can also be disabled with the sequence:

REMOTE 716
LOCAL LOCKOUT 7

After executing the code above, none of front-panel keys will respond. The analyzer can be returned to local mode temporarily with:

LOCAL 716

As soon as the analyzer is addressed to listen, it goes back into local-lockout mode. The only way to clear the local-lockout mode, aside from cycling line power, is to execute:

LOCAL 7

This command un-asserts the remote line on the interface. This puts the instrument into local mode and clears the local-lockout command. Return the instrument to remote mode by pressing:

Local TALKER/LISTENER

or

Local USE PASS CONTROL

I/O Paths

One of the features of HP BASIC is the use of input/output paths. The instrument may be addressed directly by the instrument's device number as shown in the previous examples. However, a more sophisticated approach is to declare I/O paths such as: ASSIGN @Nwa TO 716. Assigning an I/O path builds a look-up table in the computer's memory that contains the device-address codes and several other parameters. It is easy to quickly change addresses throughout the entire program at one location. I/O operation is more efficient because it uses a table, in place of calculating or searching for values related to I/O. In the more elaborate examples where file I/O is discussed, the look-up table contains all the information about the file. Execution time is decreased, because the computer no longer has to calculate a device's address each time that device is addressed.

For example:

Type SCRATCH and press (Return).

Type EDIT and press (Return).

Type in the following program:

10 ASSIGN @Nwa TO 716   Assigns the analyzer to ADDRESS 716.
20 OUTPUT @Nwa;"STAR 50 MHZ;"   Sets the analyzer's start frequency to 50 MHz.

NOTE

The use of I/O paths in binary-format transfers allows the user to quickly distinguish the type of transfer taking place. I/O paths are used throughout the examples and are highly recommended for use in device input/output.
3  GPIB Programming
Analyzer Command Syntax

Code Naming Convention

The analyzer GPIB commands are derived from their front-panel key titles (where possible), according to this naming convention:

Simple commands are the first four letters of the function they control, as in \textit{POWE}, the command name for power. If the function label contains two words, the first three mnemonic letters are the first three letters of the first word, and the fourth mnemonic letter is the first letter of the second word. For example, \textit{ELED} is derived from electrical delay.

If there are many commands grouped together in a category, as in markers or plotting pen numbers, the command is increased to 8 letters. The first four letters are the category label and the last four letters are the function specifier. As an example, category pen numbers are represented by the command \textit{PENN}, which is used in combination with several functions such as \textit{PENNDATA}, \textit{PENNMEMO}.

The code naming guidelines, listed in Table 3-1, are used in order to:

- make commands more meaningful and easier to remember
- maintain compatibility with other products (including the 8510 series analyzers)

\textbf{NOTE} There are times when these guidelines are not followed due to technical considerations.
Table 3-1 Code Naming Convention

<table>
<thead>
<tr>
<th>Convention</th>
<th>Key Title</th>
<th>For GPIB Code Use</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>One word</td>
<td>Power</td>
<td>First four letters</td>
<td>POWE</td>
</tr>
<tr>
<td></td>
<td>Start</td>
<td></td>
<td>STAR</td>
</tr>
<tr>
<td>Two words</td>
<td>ELECTRICAL DELAY</td>
<td>First three letters of first word, first letter of second word</td>
<td>ELED</td>
</tr>
<tr>
<td></td>
<td>SEARCH RIGHT</td>
<td></td>
<td>SEAR</td>
</tr>
<tr>
<td>Two words in a group</td>
<td>MARKER → CENTER</td>
<td>Four letters of both</td>
<td>MARKCENT</td>
</tr>
<tr>
<td></td>
<td>GATE → SPAN</td>
<td></td>
<td>GATESPAN</td>
</tr>
<tr>
<td>Three words</td>
<td>CAL KIT N 50 Ω</td>
<td>First three letters of first word, first letter of second word, first four letters of third word</td>
<td>CALKN50</td>
</tr>
<tr>
<td></td>
<td>PEN NUM DATA</td>
<td></td>
<td>PENNDATA</td>
</tr>
</tbody>
</table>

Some codes require appendages (ON, OFF, 1, 2, etc.). Codes that do not have a front-panel equivalent are GPIB only commands. They use a similar convention based on the common name of the function.

**Valid Characters**

The analyzer accepts the following ASCII characters:

- letters
- numbers
- decimal points
- +/–
- semicolons (;)
- quotation marks (“’)
- carriage returns (CR)
- linefeeds (LF)

Both upper- and lower-case letters are acceptable. Carriage returns, leading zeros, spaces, and unnecessary terminators are ignored, except for those within a command or appendage. If the analyzer does not recognize a character as appropriate, it generates a syntax error message and recovers at the next terminator.
Units

The analyzer can input and output data in basic units such as Hz, dB, seconds, etc.

<table>
<thead>
<tr>
<th>S</th>
<th>Seconds</th>
<th>HZ</th>
<th>Hertz</th>
</tr>
</thead>
<tbody>
<tr>
<td>V</td>
<td>Volts</td>
<td>DB</td>
<td>dB or dBm</td>
</tr>
</tbody>
</table>

Input data is assumed to be in basic units (see above) unless one of the following units is used (upper and lower case are equivalent):

<table>
<thead>
<tr>
<th>MS</th>
<th>Milliseconds</th>
<th>KHZ</th>
<th>Kilohertz</th>
</tr>
</thead>
<tbody>
<tr>
<td>US</td>
<td>Microseconds</td>
<td>MHZ</td>
<td>Megahertz</td>
</tr>
<tr>
<td>NS</td>
<td>Nanoseconds</td>
<td>GHZ</td>
<td>Gigahertz</td>
</tr>
<tr>
<td>PS</td>
<td>Picoseconds</td>
<td>FS</td>
<td>Femtoseconds</td>
</tr>
</tbody>
</table>

Command Formats

The GPIB commands accepted by the analyzer can be grouped into five input-syntax types. The analyzer does not distinguish between upper- and lower-case letters.

General Structure:

The general syntax structure is: [code][appendage][data][unit][terminator]

The individual sections of the syntax code are explained below.

[code] The root mnemonic (these codes are described in the Chapter 1, "Alphabetical Command Reference.")

[appendage] A qualifier attached to the root mnemonic. Possible appendages are ON or OFF (toggle a function on or off), or integers, which specify one capability out of several. There must be no spaces or symbols between the code and the appendage.

[data] A single operand used by the root mnemonic, usually to set the value of a function. The data can be a number or a character string. Numbers are accepted as integers or decimals, with power of ten specified by E (for example, STAR 0.2E+10; sets the start frequency to 2 GHz). Note the space between the root mnemonic and the operand. Character strings must be enclosed by double quotation marks.

For example:

A title string using RMB BASIC would look like:
OUTPUT 716;"TITL""Unit1"";"
where the first two "" are an escape so that RMB BASIC will interpret the third "" properly.

[unit] The units of the operand, if applicable. If no units are specified, the analyzer assumes the basic units as described previously. The data is entered into the function when either units or a terminator are received.
[**terminator**] Indicates the end of the command, enters the data, and switches the active-entry area off. A semicolon (;) is the recommended terminator.

---

**CAUTION** Terminators are not necessary for the analyzer to interpret commands correctly. But in the event of a syntax error, the analyzer will attempt to recover at the next terminator. Therefore, it is recommended that each command include a terminator. The analyzer also interprets line feeds and GPIB end or identify (EOI) messages as terminators.

---

**Syntax**

Each command entry listed in Chapter 1, "Alphabetical Command Reference," includes the proper syntax for the command. The conventions used are as follows:

- `<num>` Required numerical data.
- `<choice1|choice2|...|choiceN>` An appendage that is part of the command. For example, `FORMAT<DOS|LIF>` indicates that the actual commands are `FORMATDOS` and `FORMATLIF`.
- `<$>` Indicates a character string operand which must be enclosed by double quotes.
- `|` An either/or choice in appendages or optional data.
- `[ ]` Optional data.

**Syntax Example** For example, the following is provided as the syntax for the **ATT** command:

```
ATT<A|B|P1|P2><num>[DB]; or ATT<A|B|P1|P2>?
```

If you are interested in the attenuation at port 1 of the analyzer, here are some of the commands you could use:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATTP120DB;</td>
<td>Sets the attenuation at port 1 to 20 dB.</td>
</tr>
<tr>
<td>ATTP120;</td>
<td>Also sets the attenuation at port 1 to 20 dB. (Note that the units,</td>
</tr>
<tr>
<td></td>
<td>&quot;dB,&quot; are enclosed in square brackets, which designate optional</td>
</tr>
<tr>
<td></td>
<td>information.)</td>
</tr>
<tr>
<td>ATTP1?;</td>
<td>Queries the analyzer for the current attenuation at port 1.</td>
</tr>
</tbody>
</table>
Analyzer Operation

Held Commands

The analyzer cannot process GPIB commands while executing certain key commands known as “held” commands. For example, \texttt{SING;} is a held command because it requires the analyzer to take one sweep of data before executing any other commands.

Once a held command is received, the analyzer will read new commands into the input buffer, but it will not begin the execution of any commands until the completion of the held command. When the 15-character input buffer is full, the analyzer will put hold on the bus until it is able to process the commands in the buffer.

\begin{tabular}{|l|l|}
\hline
\textbf{NOTE} & Commands that call a calibration class are held if there is just one standard in the class, since such commands trigger a measurement. \\
\hline
\end{tabular}

Operation Complete

Occasionally, there is a need to know when certain analyzer operations have been completed. There is an operation-complete function (\texttt{OPC}) that allows a synchronization of programs with the execution of certain key commands. This mechanism is activated by issuing \texttt{OPC;} or \texttt{OPC?;} prior to an OPC-compatible command. The status byte or \texttt{ESR} operation-complete bit will then be set after the execution of the OPC-compatible command. For example, issuing \texttt{OPC;SING;} causes the OPC bit to be set when the single sweep is finished. Issuing \texttt{OPC?;} in place of \texttt{OPC;} causes the analyzer to output a one (1) when the command execution is complete. The analyzer will halt the computer by not transmitting the one (1) until the command has completed. For example, executing \texttt{OPC?;PRES;} and then immediately querying the analyzer causes the bus to halt until the instrument preset is complete and the analyzer outputs a one (1).

As another example, consider the timing of sweep completion. Send the command string \texttt{SWET 3 S;OPC?;SING;} to the analyzer. This string sets the analyzer sweep time to 3 seconds, and then waits for completion of a single sweep to respond with a one (1). The computer should be programmed to read the number one (1) response from the analyzer indicating completion of the single sweep. At this point a valid trace exists and the trace data could be read into the computer.

For a list of OPC-compatible commands, refer to Appendix B, “Command Listings.”
GPIB Operation

The general purpose interface bus (GPIB) is Agilent Technologies’ hardware, software, documentation, and support for IEEE 488.2 and IEC-625 worldwide standards for interfacing instruments. This interface allows you to operate the analyzer and peripherals via two methods:

- with an external system controller
- with the network analyzer in system-controller mode

Device Types

The GPIB employs a party-line bus structure in which up to 15 devices can be connected on one bus. The interface consists of 16 signal lines and 8 ground lines within a shielded cable. With this cabling system, many different types of devices including instruments, computers, power meters, plotters, printers, and disk drives can be connected in parallel.

Every GPIB device must be capable of performing one or more of the following interface functions:

**Talker**

A “talker” is a device capable of transmitting device-dependent data when addressed to talk. There can be only one active talker at any given time. Examples of this type of device include:

- power meters
- disk drives
- voltmeters
- counters
- tape readers

The network analyzer performs as a talker when it sends trace data or marker information over the bus.

**Listener**

A listener is a device capable of receiving device-dependent data over the interface when addressed to listen. There can be as many as 14 listeners connected to the interface at any given time. Examples of this type of device include:

- printers
- power supplies
- signal generators

The network analyzer performs as a listener when it is controlled over the bus by a system controller.
Controller
A controller is defined as a device capable of:

- managing the operation of the bus
- addressing talkers and listeners

There can only be one active controller on the interface at any time. Examples of controllers include desktop computers, minicomputers, workstations, and the network analyzer. In a multiple-controller system, active control can be passed between controllers, but there can only be one system controller connected to the interface. The system controller acts as the master and can regain active control at any time. The analyzer is an active controller when it plots, prints, or stores to an external disk drive in the pass-control mode. The analyzer is also a system controller when it is operating in the system controller mode.

GPIB Bus Structure

Figure 3-1  GPIB Bus Structure
Data Bus
The data bus consists of 8 bidirectional lines that are used to transfer data from one device to another. Programming commands and data transmitted on these lines are typically encoded in ASCII, although binary encoding is often used to speed up the transfer of large arrays. Both ASCII and binary data formats are available to the analyzer. In addition, every byte transferred over GPIB undergoes a handshake to insure valid data.

Handshake Lines
A three-line handshake scheme coordinates the transfer of data between talkers and listeners. To ensure data integrity in multiple-listener transfers, this technique forces data transfers to occur at the transfer rate of the slowest device connected to the interface. With most computing controllers and instruments, the handshake is performed automatically, making it transparent to the programmer.

Control Lines
The data bus also has five control lines. The controller uses these lines to address devices and to send bus commands.

IFC (Interface Clear) This line is used exclusively by the system controller. When this line is true (low), all devices (whether addressed or not) unaddress and revert to an idle state.

ATN (Attention) The active controller uses this line to define whether the information on the data bus is command-oriented or data-oriented. When this line is true (low), the bus is in the command mode, and the data lines carry bus commands. When this line is false (high), the bus is in the data mode, and the data lines carry device-dependent instructions or data.

SRQ (Service Request) This line is set true (low) when a device requests service and the active controller services the requesting device. The network analyzer can be enabled to pull the SRQ line for a variety of reasons such as requesting control of the interface, for the purposes of printing, plotting, or accessing a disk.

REN (Remote Enable) This line is used exclusively by the system controller. When this line is set true (low), the bus is in the remote mode, and devices are addressed by the controller to either listen or talk. When the bus is in remote mode and a device is addressed, it receives instructions from the system controller via GPIB rather than from its front panel (pressing Local returns the device to front-panel operation). When this line is set false (high), the bus and all of the connected devices return to local operation.

EOI (End or Identify) This line is used by a talker to indicate the last data byte in a multiple-byte transmission, or by an active controller to initiate a parallel-poll sequence. The analyzer recognizes the EOI line as a terminator, and it pulls the EOI line with the last byte of a message output (data, markers, plots, prints, error messages). The analyzer does not respond to parallel poll.
GPIB Requirements

Number of Interconnected Devices:

15 maximum.

Interconnection Path Maximum Cable Length:

20 meters maximum or 2 meters per device (whichever is less).

Message Transfer Scheme:

Byte serial, bit parallel asynchronous data transfer using a 3-line handshake system.

Data Rate:

Maximum of 1 megabyte-per-second over the specified distances with tri-state drivers. Actual data rate depends on the transfer rate of the slowest device connected to the bus.

Address Capability:

Primary addresses: 31 talk, 31 listen. A maximum of 1 talker and 14 listeners can be connected to the interface at given time.

Multiple-Controller Capability:

In systems with more than one controller (such as this instrument), only one controller can be active at any given time. The active controller can pass control to another controller, but only the system controller can assume unconditional control. Only one system controller is allowed.
**GPIB Operational Capabilities**

On the network analyzer’s rear panel, next to the GPIB connector, there is a list of GPIB device subsets as defined by the IEEE 488.2 standard. The analyzer has the following capabilities:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SH1</td>
<td>Full-source handshake.</td>
</tr>
<tr>
<td>AH1</td>
<td>Full-acceptor handshake.</td>
</tr>
<tr>
<td>T6</td>
<td>Basic talker, answers serial poll, unaddresses if MLA is issued. No talk-only mode.</td>
</tr>
<tr>
<td>L4</td>
<td>Basic listener, unaddresses if MTA is issued. No listen-only mode.</td>
</tr>
<tr>
<td>SR1</td>
<td>Complete service request (SRQ) capabilities.</td>
</tr>
<tr>
<td>RL1</td>
<td>Complete remote/local capability including local lockout.</td>
</tr>
<tr>
<td>PP0</td>
<td>Does not respond to parallel poll.</td>
</tr>
<tr>
<td>DC1</td>
<td>Complete device clear.</td>
</tr>
<tr>
<td>DT1</td>
<td>Responds to a Group Execute Trigger (GET) in the hold-trigger mode.</td>
</tr>
<tr>
<td>C1,C2,C3</td>
<td>System controller capabilities in system-controller mode.</td>
</tr>
<tr>
<td>C10</td>
<td>Pass control capabilities in pass-control mode.</td>
</tr>
<tr>
<td>E2</td>
<td>Tri-state drivers.</td>
</tr>
<tr>
<td>LE0</td>
<td>No extended listener capabilities.</td>
</tr>
<tr>
<td>TE0</td>
<td>No extended talker capabilities.</td>
</tr>
</tbody>
</table>

These codes are completely explained in the IEEE Std 488 documents, published by:

The Institute of Electrical and Electronic Engineers, Inc.
345 East 47th Street
New York, New York 11017

Or, visit their Web site at http://standards.ieee.org

**GPIB Status Indicators**

When the analyzer is connected to other instruments over the GPIB, the GPIB status indicators illuminate to display the current status of the analyzer. The GPIB status indicators are located in the instrument-state function block on the front panel of the network analyzer.

R = Remote Operation
L = Listen mode
T = Talk mode
S = Service request (SRQ) asserted by the analyzer
Bus Device Modes

The analyzer uses a single-bus architecture. The single bus allows both the analyzer and the host controller to have complete access to the peripherals in the system.

Three different controller modes are possible in an GPIB system:

- system-controller mode
- talker/listener mode
- pass-control mode

Figure 3-2 Analyzer Single Bus Concept

System-Controller Mode

This mode allows the analyzer to control peripherals directly in a stand-alone environment (without an external controller). This mode must be selected manually from the analyzer's front panel. It can only be used if no active computer or instrument controller is connected to the system via GPIB. If an attempt is made to set the network analyzer to the system-controller mode when another controller is connected to the interface, the following message is displayed on the analyzer's display screen:

"ANOTHER SYSTEM CONTROLLER ON GPIB BUS"

The analyzer must be set to the system-controller mode in order to access peripherals from the front panel. In this mode, the analyzer can directly control peripherals (plotters, printers, disk drives, power meters, etc.) and the analyzer may plot, print, store on external disk or perform power meter functions.
NOTE
Do not attempt to use this mode for programming. Agilent recommends using an external instrument controller when programming. See the following section, “Talker/Listener Mode.”

Talker/Listener Mode
This is the mode that is normally used for remote programming of the analyzer. In talker/listener mode, the analyzer and all peripheral devices are controlled from an external instrument controller. The controller can command the analyzer to talk and other devices to listen. The analyzer and peripheral devices cannot talk directly to each other unless the computer sets up a data path between them. This mode allows the analyzer to act as either a talker or a listener, as required by the controlling computer for the particular operation in progress.

Pass-Control Mode
This mode allows the computer to control the analyzer via GPIB (as with the talker/listener mode), but also allows the analyzer to take control of the interface in order to plot, print, or access a disk. During an analyzer-controlled peripheral operation, the host computer is free to perform other internal tasks (i.e. data or display manipulation) while the analyzer is controlling the bus. After the analyzer-controlled task is completed, the analyzer returns control to the system controller.

NOTE
Performing an instrument preset does not affect the selected bus mode, although the bus mode will return to talker/listener mode if the line power is cycled. To set the bus mode from the front panel, use the [Local] key.

Analyzer Bus Modes
As discussed earlier, under GPIB control, the analyzer can operate in one of three modes: talker/listener, pass-control, or system-controller mode.

In talker/listener mode, the analyzer behaves as a simple device on the bus. While in this mode, the analyzer can make a plot or print using the `OUTPLOT;` or `OUTPPRINT;` commands. The analyzer will wait until it is addressed to talk by the system controller and then dump the display to a plotter/printer that the system controller has addressed to listen. Use of the commands `PLOT;` and `PRINALL;` require control to be passed to another controller.

In pass-control mode, the analyzer can request control from the system controller and take control of the bus if the controller addresses it to take control. This allows the analyzer to take control of printers, plotters, and disk drives on an as-needed basis. The analyzer sets event-status register bit 1 when it needs control of the interface, and the analyzer will transfer control back to the system controller at the completion of the operation. It will pass control back to its controller address, specified by `ADDRCONT`.  

Chapter 3  3-13
The analyzer can also operate in the system-controller mode. This mode is only used when there is no remote controller on the bus. In this mode, the analyzer takes control of the bus, and uses it whenever it needs to access a peripheral. While the analyzer is in this mode, no other devices on the bus can attempt to take control. Specifically, the REN, ATN, and IFC lines must remain unasserted, and the data lines must be freed by all but the addressed talker.

**Setting GPIB Addresses**

In systems interfaced using GPIB, each instrument on the bus is identified by an GPIB address. This address code must be different for each instrument on the bus. These addresses are stored in short-term, non-volatile memory and are not affected when you press \( \text{Preset} \) or cycle the power. The analyzer occupies two GPIB addresses: the instrument itself and the display. The display address is derived from the instrument address by complementing the instrument's least-significant bit. Hence, if the instrument is at an even address, the display occupies the next higher address. If the instrument is at an odd address, the display occupies the next lower address.

The analyzer addresses are set by pressing \( \text{Local SET ADDRESSES} \). In system-controller mode, the addresses must be set for the plotter, printer, disk drive, and power meter.

The default address for the analyzer is device 16, and the display address is device 17.

---

**NOTE**

There is also an address for the system controller. This address refers to the controller when the network analyzer is being used in pass-control mode. This is the address that control is passed back to when the analyzer-controlled operation is complete.

---

**Response to GPIB Meta-Messages**

(IEEE-488 Universal Commands)

**Abort**

The analyzer responds to the abort message (IFC) by halting all listener, talker, and controller functions.

**Device Clear**

The analyzer responds to the device clear commands (DCL, SDC) by clearing the input and output queues, and clearing any GPIB errors. The status registers and the error queue are unaffected.

**Local**

The analyzer will go into local mode if the local command (GTL) is received, the remote line is unasserted, or the front-panel local key is pressed. Changing the analyzer's GPIB status from remote to local does not affect any of the front-panel functions or values.
Local Lockout
If the analyzer receives the local-lockout command (LLO) while it is in remote mode, it will disable the entire front panel except for the line power switch. A local-lockout condition can only be cleared by releasing the remote line, although the local command (GTL) will place the instrument temporarily in local mode.

Parallel Poll
The analyzer does not respond to parallel-poll configure (PPC) or parallel-poll unconfigure (PPU) messages.

Pass Control
If the analyzer is in pass-control mode, is addressed to talk, and receives the take-control command (TCT), from the system control it will take active control of the bus. If the analyzer is not requesting control, it will immediately pass control to the system controller’s address. Otherwise, the analyzer will execute the function for which it sought control of the bus and then pass control back to the system controller.

Remote
The analyzer will go into remote mode when the remote line is asserted and the analyzer is addressed to listen. While the analyzer is held in remote mode, all front-panel keys (with the exception of Local) are disabled. Changing the analyzer’s GPIB status from remote to local does not affect any front-panel settings or values.

Serial Poll
The analyzer will respond to a serial poll with its status byte, as defined in “Status Reporting” on page 6-3. To initiate the serial-poll sequence, address the analyzer to talk and issue a serial-poll enable command (SPE). Upon receiving this command, the analyzer will return its status byte. End the sequence by issuing a serial-poll disable command (SPD). A serial poll does not affect the value of the status byte, and it does not set the instrument to remote mode.

Trigger
In hold mode, the analyzer responds to device trigger by taking a single sweep. The analyzer responds only to selected-device trigger (SDT). This means that it will not respond to group execute-trigger (GET) unless it is addressed to listen. The analyzer will not respond to GET if it is not in hold mode.
IEEE 488.2 Common Commands

IEEE 488.2 defines a set of common commands. All instruments are required to implement a subset of these commands, specifically those commands related to status reporting, synchronization and internal operations. The rest of the common commands are optional. The following list details which of these IEEE 488.2 common commands are implemented in the analyzer and the response of the analyzer when the command is received.

*CLS
Clears the instrument Status Byte by emptying the error queue and clearing all event registers, also cancels any preceding *OPC command or query (does not change the enable registers or transition filters).

*ESE <num>
Sets bits in the Standard Event Status Enable Register — current setting is saved in non-volatile memory.

*ESE?
Reads the current state of the Standard Event Status Enable Register.

*ESR?
Reads and clears the current state of the Standard Event Status Register.

*IDN?
Returns a string that uniquely identifies the analyzer. The string is of the form:
HEWLETT PACKARD,87NNE,0,X.XX
where 87NNE is the model number of the instrument and X.XX is the firmware revision of the instrument.

*LRN?
This returns a string of device specific characters that, when sent back to the analyzer will restore the instrument state active when *LRN? was sent. Data formatting (ENTER USING “-K” in HP BASIC) or a similar technique should be used to ensure that the transfer does not terminate on a carriage return or line feed (both <CR> and <LF> are present in the learn string as part of the data).

*OPC
Operation complete command. The analyzer will generate the OPC message in the Standard Event Status Register when all pending overlapped operations have been completed (e.g. a sweep, or a preset).

*OPC?
Operation complete query. The analyzer will return an ASCII “1” when all pending overlapped operations have been completed.

*PCB <num>
Sets the pass-control-back address (the address of the controller before a pass control is executed).

*RST
Executes a device reset and cancels any pending *OPC command or query.

*SRE <num>
Sets bits in the Service Request Enable Register. Current setting is saved in non-volatile memory.

*SRE?
Reads the current state of the Service Request Enable Register.

*STB?
Reads the value of the instrument Status Byte. This is a non-destructive read—the Status Byte is cleared by the *CLS command.
GPIB Programming

Calibration

*WAI Prohibits the instrument from executing any new commands until all pending overlapped commands have been completed.

---

**Calibration**

Measurement calibration over GPIB follows the same command sequence as a calibration from the front-panel. For detailed information on measurement calibration, refer to your analyzer's user's guide.

1. Start by selecting a calibration kit, such as 50 ohm type-N (**CALKN50**;).
2. Select a calibration type, such as S11 1-port (**CALIS111**;).
3. Call each class used by the calibration type, such as FORWARD: OPEN (**CLASS11A**;)
   During a 2-port calibration, the reflection, transmission, and isolation subsequences must be opened before the classes in the subsequence are called, and then closed at the end of each subsequence.
4. If a class has more than one standard in it, select a standard from the menu presented (**STANA to STANG**).
5. If, during a calibration, two standards are measured to satisfy one class, the class must be closed with **DONE**;
6. Declare the calibration done, such as with **DONE 1-PORT CAL** (**SAV1**;).

The **STANA to STANG** commands will hold off the GPIB until completion because they trigger a sweep. If a class has only one standard in it, which means that it will trigger a sweep when called, the class command will also hold off the GPIB.

---

**NOTE** Since different cal kits can have a different number of standards in a given class, any automated calibration sequence is valid only for a specific cal kit.

1. One path, 2-port cal duplicates arrays 1 to 6 in arrays 7 to 12.
2. Response and isolation corrects for crosstalk and transmission tracking in transmission measurements, and for directivity and reflection tracking in reflection measurements.
3. This term is used to generate the calibration coefficients, but is not used during measurement error correction.

**Meaning of first subscript:**
- D: directivity
- S: source match
- R: reflection tracking
- X: crosstalk or isolation
- L: load match
- T: transmission tracking

**Meaning of second subscript:**
- F: forward
- R: reverse
Display Graphics

User Graphics Units
Size of graticule only:
- length = 350 to 4915
- height = 150 to 3950

Size of complete display (graticule plus annotation and softkey labels)
- length = 0 to 5850
- height = 0 to 4095

HP-GL Commands

AF
Erases the user graphics display.

CS
Turns off the measurement display.

DI<run>,<rise>
Specifies the direction in which characters are lettered.

<table>
<thead>
<tr>
<th>run,rise</th>
<th>Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>1,0</td>
<td>0 degrees</td>
</tr>
<tr>
<td>0,1</td>
<td>90 degrees</td>
</tr>
<tr>
<td>-1,0</td>
<td>180 degrees</td>
</tr>
<tr>
<td>0,-1</td>
<td>270 degrees</td>
</tr>
</tbody>
</table>

DF
Sets the default values.

LB <text><etx>
Labels the display, placing the symbols starting at the current pen position. All incoming characters are printed until the etx symbol is received. The default etx symbol is the ASCII value 3 (not the character 3).
**LTa**
Specifies line type:

<table>
<thead>
<tr>
<th>a</th>
<th>line type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>solid</td>
</tr>
<tr>
<td>1</td>
<td>solid</td>
</tr>
<tr>
<td>2</td>
<td>short dashes</td>
</tr>
<tr>
<td>3</td>
<td>long dashes</td>
</tr>
</tbody>
</table>

**OP**
Outputs P1 and P2, the scaling limits: 0,0,5850,4095.

**PAx,y**
Draws from the current pen position to x,y. There can be many pairs of x,y coordinates within one command. They are separated by commas, and the entire sequence is terminated with a semicolon.

**PD**
Pen down. A line is drawn only if the pen is down.

**PG**
Erases the user graphics display.

**PRx,y**
Plot relative: draws a line from the current pen position to a position y up and x over.

**PU**
Pen up. Stops anything from being drawn.

**RS**
Turns on the measurement display.

**SIh,w**
Sets the character size, for height h and width w in centimeters:

<table>
<thead>
<tr>
<th>h</th>
<th>w</th>
<th>char size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.16</td>
<td>0.20</td>
<td>smallest</td>
</tr>
<tr>

## Disk File Names

Disk files created by the analyzer consist of a state name of up to eight characters, such as “FILTER,” appended with up to two characters. In LIF format, the file name is “FILTERXX.” In DOS format, the filename is “FILTER.XX.” The first appended character is the file type, telling the kind of information in the file. The second appended character is a data index, used to distinguish files of the same type.

Error-corrected data, raw data, formatted data, memory traces, and calibration files are FORM 3 data files (IEEE 64-bit floating point format). The other files are not meant to be decoded. Table 3-4 lists the appended characters and their meanings.

4 Reading Analyzer Data
Output Queue

Whenever an output-data command is received, the analyzer puts the data into the output queue (or buffer) where it is held until the system controller outputs the next read command. The queue, however, is only one event long: the next output-data command will overwrite the data already in the queue. Therefore, it is important to read the output queue immediately after every query or data request from the analyzer.

Command Query

All instrument functions can be queried to find the current on/off state or value. For instrument state commands, append the question mark character (?) to the command to query the state of the functions. Suppose the operator has changed the power level from the analyzer's front panel. The computer can ascertain the new power level using the analyzer's command-query function. If a question mark is appended to the root of a command, the analyzer will output the value of that function. For instance, `POWE 7DB;` sets the source power to 7 dB, and `POWE?;` outputs the current RF source power at the test port. When the analyzer receives `POWE?;`, it prepares to transmit the current RF source power level. This condition illuminates the analyzer front-panel talk light (T). In this case, the analyzer transmits the output power level setting to the controller.

On/off commands can also be queried. The reply is a one (1) if the function is on, or a zero (0) if it is off. For example, if a command controls an active function that is underlined on the analyzer display, querying that command yields a one (1) if the command is underlined or a zero (0) if it is not. As another example, there are nine options on the format menu and only one option is underlined at a time. Only the underlined option will return a one when queried.

For instance, send the command string `DUAC?;` to the analyzer. If dual-channel display is switched on, the analyzer will return a one (1) to the instrument controller.

Similarly, to determine if phase is being measured and displayed, send the command string `PHAS?;` to the analyzer. In this case, the analyzer will return a one (1) if phase is currently being displayed. Since the command only applies to the active channel, the response to the `PHAS?;` query depends on which channel is active.

Identification

The analyzer's response to `IDN?;` is “HEWLETT PACKARD, 87NNEX, xxxxxxxxxx, X.XX” where 87NNEX is the model number of the instrument, xxxxxxxxxx is the serial number, and X.XX is the firmware revision of the instrument.

The analyzer also has the capability to output its serial number with the command `OUTPSERN;`, and to output its installed options with the command `OUTPOPTS;`.
Output Syntax

The following three types of data are transmitted by the analyzer in ASCII format:

- response to query
- certain output commands
- ASCII floating-point (FORM4) array transfers

Marker-output commands and queried commands are output in ASCII format only, meaning that each character and each digit is transmitted as a separate byte, leaving the receiving computer to reconstruct the numbers and strings. Numbers are transmitted as 24-character strings, consisting of:

**Figure 4-1  FORM4 (ASCII) Data-Transfer Character String**

| Sign | ‘−’ for negative, blank for positive. |
| 3 digits | Digits to the left of the decimal point. |
| Decimal Point | Standard decimal point. |
| 15 digits | Digits to the right of the decimal point. |
| E | Exponent notation. |
| Sign (in exponent) | ‘−’ for negative, ‘+’ for positive. |
| Exponent | Two digits for the exponent. |

When multiple numbers are sent, the numbers are separated by commas. When number pairs are sent, the numbers are separated by a comma and terminated with a line feed, \(<LF>\).
Marker Data

The analyzer offers several options for outputting trace-related data. Data can be selectively read from the trace using the markers, or the entire trace can be read by the controller. If only specific information is required (such as a single point on the trace or the result of a marker search), the marker output command can be used to read the information. Specific data points can be read using the \texttt{OUTPDAIP} or \texttt{OUTPDAIR} commands. These commands allow a much faster data transfer than when using markers to output specific data points. For more information on these commands, see "Limit Line and Data Point Special Functions" on page 7-126.

A marker must first be assigned to the desired frequency before it can be used to read the trace data. This is accomplished using the marker commands. The controller sends a marker command followed by a frequency within the trace-data range. If the actual desired frequency was not sampled, the markers can be set to continuous mode and the desired marker value will be linearly interpolated from the two nearest points. This interpolation can be prevented by putting the markers into discrete mode. Discrete mode allows the marker to only be positioned on a measured trace-data point.

As an alternative, the analyzer can be programmed to choose the stimulus value by using the \texttt{Function} functions. Maximum, minimum, target value, or bandwidth search can be automatically determined with \texttt{Function} functions. To continually update the search, switch the marker tracking on. The trace-value search will remain activated until one of the following occurs:

- The search is switched off.
- The tracking is switched off.
- All markers are switched off.

Marker data can be output to a controller by using analyzer commands. These commands cause the analyzer to transmit three numbers: marker value 1, marker value 2, and marker stimulus value. For example, in log-magnitude display mode we get the log magnitude at the marker (value 1), zero (value 2), and the marker frequency. See \texttt{Function} for a complete listing of all the possibilities for values 1 and 2. The four possibilities for the marker stimulus value are:

- frequency
- time (as in time domain, Option 010 only)
- CW time

1. The marker readout values are the marker values displayed in the upper right-hand corner of the display. They also correspond to the value and auxiliary value associated with the fixed marker.
2. Value 2 is not significant in this format, though is included in data transfers. See also “Fast Data Transfer Commands” on page 5-5.
**Array-Data Formats**

The analyzer can transmit and receive arrays in the analyzer’s internal binary format as well as four different numeric formats. The current format is set with the FORM1, FORM2, FORM3, FORM4, and FORM5 commands. These commands do not affect learnstring transfers, calibration-kit string transfers, or non-array transfers, such as command query, or output marker values.

A transmitted array will be output in the current format, and the analyzer will attempt to read incoming arrays according to the current format. Each data point in an array is a pair of numbers, usually a real/imaginary pair. The number of data points in each array is the same as the number of points in the current sweep.

The five formats are described below:

**FORM1**
The analyzer’s internal binary format, 6 bytes-per-data point. The array is preceded by a four-byte header. The first two bytes represent the string “#A”, the standard block header. The second two bytes are an integer representing the number of bytes in the block to follow. FORM1 is best applied when rapid data transfers, not to be modified by the computer nor interpreted by the user, are required.

**FORM2**
IEEE 32-bit floating-point format, 4 bytes per number, 8 bytes-per-data point. The data is preceded by the same header as in FORM1. Each number consists of a 1-bit sign, an 8-bit biased exponent, and a 23-bit mantissa. FORM2 is the format of choice if your computer is not a PC, but supports single-precision floating-point numbers.

**FORM3**
IEEE 64-bit floating-point format, 8 bytes per number, 16 bytes-per-data point. The data is preceded by the same header as in FORM1. Each number consists of a 1-bit sign, an 11-bit biased exponent, and a 52-bit mantissa. This format may be used with double-precision floating-point numbers. No additional precision is available in the analyzer data, but FORM3 may be a convenient form for transferring data to your computer.

**FORM4**
ASCII floating-point format. The data is transmitted as ASCII numbers, as described previously in “Output Syntax” on page 4-3. There is no header. The analyzer always uses FORM4 to transfer data that is not related to array transfers (i.e. marker responses and instrument settings).

**FORM5**
PC-DOS 32-bit floating-point format with 4 bytes-per-number, 8 bytes-per-data point. The data is preceded by the same header as in FORM1. The byte order is reversed with respect to FORM2 to comply with PC-DOS formats. If you are using a PC-based controller, FORM5 is the most effective format to use.

The analyzer terminates each transmission by asserting the EOI interface line with the last byte transmitted. **Table 4-2** offers a comparative overview of the five array-data formats.

Trace-Data Transfers

Transferring trace-data from the analyzer using an instrument controller can be divided into three steps:

1. Allocating an array to receive and store the data
2. Commanding the analyzer to transmit the data
3. Accepting the transferred data

Data residing in the analyzer is always stored in pairs for each data point (to accommodate real/imaginary pairs). Hence, the receiving array must be two elements wide, and as deep as the number of points in the array being transferred. Memory space for the array must be declared before any data can be transferred from the analyzer to the computer.

As mentioned earlier, the analyzer can transmit data over GPIB in five different formats. The type of format affects what kind of data array is declared (real or integer), because the format determines what type of data is transferred. Programming examples of data transfers using different formats are discussed in “Measurement Data Transfer Examples” on page 7-56. For information on the various types of data that can be obtained (raw data, error-corrected data, etc.), see “Data Levels” on page 5-6.

For information on transferring trace-data by selected points, see “Limit Line and Data Point Special Functions” on page 7-126.

NOTE

“Example 7F: Reading ASCII Disk Files to the Instrument Controller’s Disk File” on page 7-118 explains how to access disk files from a computer.
Stimulus-Related Values

Frequency-related values are calculated for the analyzer display. The start and stop frequencies or center and span frequencies of the selected frequency range are available to the programmer.

In a linear frequency range, the frequency values can be easily calculated because the trace data points are equally spaced across the trace. Relating the data from a linear frequency sweep to frequency can be done by querying the start frequency, the frequency span, and the number of points in the trace.

Given that information, the frequency of point \( n \) in a linear-frequency sweep is represented by the equation:

\[
F = \text{StartFrequency} + (n - 1) \times \frac{\text{Span}}{(\text{Points} - 1)}
\]

In most cases, this is an easy solution for determining the related frequency value that corresponds with a data point. This technique is illustrated in “Example 3B: Data Transfer Using FORM 4 (ASCII Transfer)” on page 7-59.

When using log sweep or a list-frequency sweep, the points are not evenly spaced over the frequency range of the sweep. In these cases, an effective way of determining the frequencies of the current sweep is to use the \texttt{OUTPLIML} command. Although this command is normally used for limit lines, it can also be used to identify all of the frequency points in a sweep. Limit lines do not need to be on in order to read the frequencies directly out of the instrument with the \texttt{OUTPLIML} command. Refer to “Example 3D: Data Transfer Using Frequency-Array Information” on page 7-64.

\textbf{NOTE} Another method of identifying all of the frequency points in a sweep is to use the marker commands \texttt{MARKBUCK\( <\text{num}> \)} and \texttt{OUTPMARK} in a “FOR NEXT” programming loop that corresponds to the number of points in the sweep. \texttt{MARKBUCK\( <\text{num}> \)} places a marker at a point in the sweep, where \( <\text{num}> \) is the number of the point in a sweep, and \texttt{OUTPMARK} outputs the stimulus value as part of the marker data.
Reading Analyzer Data

Stimulus-Related Values
5 Data Processing Chain
Using This Chapter

This chapter describes the manner in which the analyzer processes measurement data. Measurement data processes include:

- “Data Arrays” on page 5-3
- “Common Output Commands” on page 5-4
- “Fast Data Transfer Commands” on page 5-5
- “Data Levels” on page 5-6
- “Learn String and Calibration-Kit String” on page 5-7

NOTE Refer to “OUTP” on page 1-154 for detailed information (such as proper syntax) for the output commands discussed in this chapter.
Data Arrays

Figure 5-1 shows the different kinds of data available within the instrument:

- pre-raw measured data
- raw measured data
- error-corrected data
- formatted data
- trace memory
- calibration coefficients

Trace memory can be directly output to a controller with OUTPMEMO, but it cannot be directly transmitted back.

Figure 5-1 The Data-Processing Chain For Measurement Outputs
Common Output Commands

All the data-output commands are designed to insure that the data transmitted reflects the current state of the instrument:

• **OUTPDATA, OUTPRAW, OUTPFORM, OUTPDATE, OUTPRAWF and OUTPFORF** will not transmit data until all formatting functions have completed.

• **OUTPPRE** transmits data in conjunction with Take4 mode and the SWPSTART command. Refer to “Example 2G: Take4 — Error Correction Processed on an External PC” on page 7-48.

• **OUTPLIML, OUTPLIMM, and OUTPLIMF** will not transmit data until the limit test has occurred (if activated).

• **OUTPMARK** will activate a marker if a marker is not already selected. It will also insure that any current marker searches have been completed before transmitting data.

• **OUTPMSTA** ensures that the statistics have been calculated for the current trace before transmitting data. If the statistics are not activated, it will activate the statistics long enough to update the current values before deactivating the statistics.

• **OUTPMWID** ensures that a bandwidth search has been executed for the current trace before transmitting data. If the bandwidth-search function is not activated, it will activate the bandwidth-search function long enough to update the current values before switching off the bandwidth-search functions.
Fast Data Transfer Commands

The analyzer has four distinct fast data transfer commands. These commands circumvent the internal “byte handler” routine and output trace dumps as block data. In other words, the analyzer outputs the entire array without allowing any process swapping to occur. FORM4, ASCII data transfer times are not affected by these routines. However, there are speed improvements with binary data formats. The following is a description of the four fast data transfer commands:

- **OUTPDATF** outputs the error corrected data from the active channel in the current output format. This data may be input to the analyzer using the **INPUDATA** command.

- **OUTPFORF** outputs the formatted display trace array from the active channel in the current output format. Only the first number in each of the **OUTPFORM** data pairs is actually transferred for the display formats LOG MAG, PHASE, group DELAY, LIN MAG, SWR, REAL and IMAGinary. Because the data array does not contain the second value for these display formats, the **INPUIFORM** command may not be used to re-input the data back into the analyzer. The second value may not be significant in some display formats (see Table 4-1 on page 4-5) thus reducing the number of bytes transferred.

- **OUTPMEMF** outputs the memory trace from the active channel. The data is in real/imaginary pairs, and, as such, may be input back into the memory trace using **INPUDATA** or **INPUFORM** followed by the **DATI** command.

- **OUTPRAF** outputs the raw measurement data trace. The data may be input back into the memory trace using the **INPURAW** command.
Data Levels

Different levels of data can be read out of the instrument. Refer to the data-processing chain in Figure 5-1. The following sections describe the different types of data that are available from the network analyzer.

Pre-Raw Data

This is the raw data without sampler correction or attenuator offsets applied. With raw offsets turned off, the calibration coefficients generated can be transferred to an external controller and used with the data gathered using the OUTPRE commands. Refer to “Example 2G: Take4 — Error Correction Processed on an External PC” on page 7-48. If a 2-port measurement calibration is active, or Take4 mode is on, the four arrays refer to $S_{11}$, $S_{21}$, $S_{12}$, and $S_{22}$ respectively. This data is represented in real/imaginary pairs.

Raw Data

The basic measurement data, reflecting the stimulus parameters, IF averaging, and IF bandwidth. If a full 2-port measurement calibration is activated, there are actually four raw arrays kept: one for each raw S-parameter. The data can be output to a controller with the OUTPRAW commands. Normally, only raw 1 is available, and it holds the current parameter. If a 2-port measurement calibration is active, the four arrays refer to $S_{11}$, $S_{21}$, $S_{12}$, and $S_{22}$ respectively. This data is represented in real/imaginary pairs.

Error Coefficients

The results of a measurement calibration are arrays containing error coefficients. These error coefficients are then used in the error-correction routines. Each array corresponds to a specific error term in the error model. Your analyzer’s user’s guide details which error coefficients are used for specific calibration types, as well as the arrays those coefficients can be found in. Not all calibration types use all 12 arrays. The data is stored as real/imaginary pairs.

Error-Corrected Data

This is the raw data with error-correction applied. The array represents the currently measured parameter, and is stored in real/imaginary pairs. The error-corrected data can be output to a controller with the OUTPDATA; command. The OUTPMEMO; command reads the trace memory, if available. The trace memory also contains error-corrected data. Note that neither raw nor error-corrected data reflect such post-processing functions as electrical-delay offset, trace math, or time-domain gating.
Data Processing Chain

Learn String and Calibration-Kit String

**Formatted Data**

This is the array of data actually being displayed. It reflects all post-processing functions such as electrical delay and time domain. The units of the array output depend on the current display format. See Table 4-1 on page 4-5 for the various units defined as a function of display format.

Generally, formatted data is the most useful of the five data levels, because it is the same information the operator sees on the display. However if post-processing is unnecessary (such as in some cases involving smoothing), error-corrected data may be more desirable. Error-corrected data also affords the user the opportunity to input the data to the network analyzer and apply post-processing at another time.

---

**Learn String and Calibration-Kit String**

The learn string is a summary of the instrument state. It includes all the front-panel settings, the limit-test tables, and the list-frequency table for the current instrument state. It does not include calibration data or the information stored in the save/recall registers.

The learn string can be output to a controller with the `OUTPLEAS;` command, which commands the analyzer to start transmitting the binary string. The string has a fixed length for a given firmware revision. The array has the same header as in FORM 1. Refer to “Example 5A: Using the Learn String” on page 7-79.

The calibration kit includes a set of key characteristics of the calibration standards used to determine the calibration accuracy. There are default kits for several different connector types. There is also space for a user-defined calibration kit. The command `OUTPCALK` outputs the currently active calibration kit as a binary string in FORM 1. As with the learn string, the calibration-kit string has a fixed length for a given firmware revision.
Data Processing Chain

Learn String and Calibration-Kit String
6 Error Reporting
Using This Chapter

This chapter describes the analyzer's error-reporting process. The error-reporting processes include:

- "Status Reporting" on page 6-3
- "The Status Byte" on page 6-6
- "The Event-Status Register and Event-Status Register B" on page 6-7
- "Error Output" on page 6-8
- "Error Messages in Numerical Order" on page 6-9
Status Reporting

The analyzer status reporting structure is depicted in Figure 6-1. Refer to Table 6-1, Table 6-2, and Table 6-3 for a description of each bit within the status reporting structure.

The Status Byte

The analyzer has a status-reporting mechanism that reports information about specific analyzer functions and events. The status byte (consisting of summary bits) is the top-level register (see Figure 6-1). Each bit reflects the condition of another register or queue. If a summary bit is set (equals 1), the corresponding register or queue should be read to obtain the status information and clear the condition. Reading the status byte does not affect the state of the summary bits. The summary bits always reflect the condition of the summarized queue or register.

The status byte can be read by a serial poll or by using the command `OUTPSTAT`. `OUTPSTAT` does not automatically put the instrument in remote mode, thus giving the operator access to the analyzer front-panel functions. `OUTPSTAT` will return an ASCII (text) integer (0–255) that can be interpreted as the 8-bit status byte. Using the `OUTPSTAT` command will not necessarily return the same status byte value as when using a serial poll because the “Message in Output Queue” bit is always set when using `OUTPSTAT`.

The status byte:

- summarizes the error queue
- summarizes two event-status registers that monitor specific conditions inside the instrument
- contains a bit that is set when the instrument is issuing a service request (SRQ) over GPIB
- contains a bit that is set when the analyzer has data to transmit over GPIB

Any bit in the status byte can be selectively enabled to generate a service request (SRQ) when set. Setting a bit in the service-request-enable register with the `SRE nn` command enables the corresponding bit in the status byte. The units variable `nn` represents the binary equivalent of the bit in the status byte. For example, `SRE24;` enables status-byte bits 3 and 4 (since $2^3 + 2^4 = 24$) and disables all the other bits. `SRE` will not affect the state of the status-register bits.

The sequencing bit can be set during the execution of a test sequence to assert an SRQ.

The status byte also summarizes two queues: the output queue and the error queue. The error queue is described in the next section.) When the analyzer outputs information, it puts the information in the output queue where it resides until the controller reads it. The output queue is only one event long. Therefore, the next output request will clear the current data. The summary bit is set whenever there is data in the output queue.
The Event-Status Register and Event-Status Register B

The event-status register and event-status register B are the other two registers in the status-reporting structure (see Figure 6-1). They are selectively summarized by bits in the status byte via enable registers. The event-status registers consist of latched bits. A latched bit is set at the beginning of a specific trigger condition in the instrument. It can only be cleared by reading the register. The bit will not be reactivated until the condition occurs again. If a bit in one of these two registers is enabled, it is summarized by the summary bit in the status byte. The registers are enabled using the commands \texttt{ESE\text{\textsubscript{n}n};} and \texttt{ESB\text{\textsubscript{n}n};}, both of which work in the same manner as \texttt{SRE\text{\textsubscript{n}n}}. The units variable \textit{nn} represents the binary equivalent of the bit in the status byte.

If a bit in one of the event-status registers is enabled, and therefore, the summary bit in the status byte is enabled, an SRQ will be generated. The SRQ will not be cleared until one of the five following conditions transpire:

- The event-status register is read, clearing the latched bit.
- The summary bit in the status byte is disabled.
- The event-status register bit is disabled.
- The status registers are cleared with the \texttt{CLES;} command.
- An instrument preset is performed.

Service requests generated when there are error messages or when the instrument is waiting for the group execute trigger (GET) command are cleared by:

- reading the errors
- issuing \texttt{GET} (disabling the bits)
- clearing the status registers
Error Output

When an error condition is detected in the analyzer, a message is generated, displayed on the analyzer’s display screen, and placed in the error queue. Error messages consist of an error number followed by an ASCII string no more than 50 characters long. The string contains the same message that appears on the analyzer’s display. The error queue holds up to 20 error messages in the order in which they occur. The error messages remain in the error queue until the errors are read by the system controller using the command OUTPERRO. The OUTPERRO command outputs one error message.

NOTE  The error queue can only be cleared by performing an instrument preset or by cycling the line power. In order to keep the queue up-to-date, it is important to read all of the messages out of the queue each time errors are detected.
## Error Messages in Numerical Order

For explanations and suggestions in finding the cause of the error messages, refer to your analyzer’s reference guide. Some error numbers have been omitted due to obsoleted error messages.

7 Programming Examples
Using This Chapter

This chapter provides explanations and listings for the example programs that are included on the “Programming Examples” CD-ROM (part number 08753-10039) that accompanied this manual. A description of the typical measurement process is also included in the “Measurement Process” section, starting on page 7-3.

All of the examples on the CD-ROM are provided in HP BASIC, and most are also provided in Visual C++ and Visual BASIC for use with the provided VXI plug&play driver. See Chapter 2, “Introduction to Instrument Control,” for information on using HP BASIC, and installing and using the VXI plug&play driver.

NOTE

“Example 1A: Setting Parameters” on page 7-10 includes program listings for HP BASIC, Visual C++, and Visual BASIC. These listings are provided for you to see a comparison of the different programming languages. The rest of the examples in this manual only include the HP BASIC listing. You can readily view all of the programs by accessing the CD-ROM that was shipped with this manual. The programs are in the following three directories on the CD-ROM:

- \\hpbasic (HP BASIC programs)
- \\vc (Visual C++ programs)
- \\vb (Visual BASIC programs)
Measurement Process

This section explains how to organize instrument commands into a measurement sequence. A typical measurement sequence consists of the following steps:

1. setting up the instrument
2. calibrating the test setup
3. connecting the device under test
4. taking the measurement data
5. post-processing the measurement data
6. transferring the measurement data

Step 1. Setting Up the Instrument

Define the measurement by setting all of the basic measurement parameters. These include:

- the sweep type
- the frequency span
- the sweep time
- the number of points (in the data trace)
- the RF power level
- the type of measurement
- the IF averaging
- the IF bandwidth

You can quickly set up an entire instrument state, using the save/recall registers and the learn string. The learn string is a summary of the instrument state compacted into a string that the computer reads and retransmits to the analyzer. See “Example 5A: Using the Learn String” on page 7-79.

Step 2. Calibrating the Test Setup

After you have defined an instrument state, you should perform a measurement calibration. Although it is not required, a measurement calibration improves the accuracy of your measurement data.

The following list describes several methods to calibrate the analyzer:

- Stop the program and perform a calibration from the analyzer's front panel.
- Use the computer to guide you through the calibration, as discussed in “Measurement Calibration Examples” on page 7-23.
- Transfer the calibration data from a previous calibration back into the analyzer, as discussed in “Example 5C: Saving and Restoring the Analyzer Instrument State” on page 7-84.
**Step 3. Connecting the Device under Test**

After you connect your test device, you can use the computer to speed up any necessary device adjustments such as limit testing, bandwidth searches, and trace statistics.

**Step 4. Taking the Measurement Data**

Measure the device response and set the analyzer to hold the data. This captures the data on the analyzer display.

By using the single-sweep command (**SING**), you can ensure a valid sweep. When you use this command, the analyzer completes all stimulus changes before starting the sweep, and does not release the GPIB hold state until it has displayed the formatted trace. Then when the analyzer completes the sweep, the instrument is put into hold mode, freezing the data. Because single sweep is OPC-compatible, it is easy to determine when the sweep has been completed.

The number-of-groups command (**NUMGn**) triggers multiple sweeps. It is designed to work the same as single-sweep command. **NUMGn** is useful for making a measurement with an averaging factor \( n \) (\( n \) can be 1 to 999). Both the single-sweep and number-of-groups commands restart averaging.

**Step 5. Post-Processing the Measurement Data**

**Figure 5-1 on page 5-3** shows the process functions used to affect the data after you have made an error-corrected measurement. These process functions have parameters that can be adjusted to manipulate the error-corrected data prior to formatting. They do not affect the analyzer’s data gathering. The most useful functions are trace statistics, marker searches, electrical-delay offset, time domain, and gating.

After performing and activating a full 2-port measurement calibration, any of the four S-parameters may be viewed without taking a new sweep (ES models only).

**Step 6. Transferring the Measurement Data**

Read your measurement results. All the data-output commands are designed to ensure that the data transmitted reflects the current state of the instrument.
# Programming Examples

The following example programs provide you with factory-tested solutions for several remotely-controlled analyzer processes. The programs can be used in their present state or modified to suit specific needs. The programs discussed in this section can be found on the “Programming Examples” CD-ROM that was shipped with this manual.

Program Information

The following information is provided for every HP BASIC example program included on the “Programming Examples” CD-ROM:

- A program description
- An outline of the program's processing sequence
- A step-by-step instrument-command-level tutorial explanation of the program including:
  - The command mnemonic and command name for the GPIB instrument command used in the program.
  - An explanation of the operations and affects of the GPIB instrument commands used in the program.

Analyzer Features Helpful in Developing Programming Routines

Analyzer-Debug Mode

The analyzer-debug mode aids you in developing programming routines. The analyzer displays the commands being received. If a syntax error occurs, the analyzer displays the last buffer and points to the first character in the command line that it could not understand.

You can enable this mode from the front panel by pressing [Local] GPIB DIAG ON. The debug mode remains activated until you preset the analyzer or deactivate the mode. You can also enable this mode over the GPIB using the DEBUON; command and disable the debug mode using the DEBUOFF; command.

User-Controllable Sweep

There are three important advantages to using the single-sweep mode:

1. The user can initiate the sweep.
2. The user can determine when the sweep has completed.
3. The user can be confident that the trace data has be derived from a valid sweep.

Execute the command string OPC?;SING; to place the analyzer in single-sweep mode and trigger a sweep. Once the sweep is complete, the analyzer returns an ASCII character one (1) to indicate the completion of the sweep.
NOTE  The measurement cycle and the data acquisition cycle must always be synchronized. The analyzer must complete a measurement sweep for the data to be valid.
Measurement Setup Examples

The programs included in this section provide the option to perform instrument-setup functions for the analyzer from a remote controller. Example 1A is a program designed to set up the analyzer’s measurement parameters. Example 1B is a program designed to verify the measurement parameters.

Example 1A: Setting Parameters

In general, the procedure for setting up measurements on the network analyzer via GPIB follows the same sequence as if the setup was performed manually. There is no required order, as long as the desired frequency range, number of points, and power level are set prior to performing the calibration first, and the measurement second.

This example sets the following parameters:

- data display formats
- number of channels displayed, and number of graticules to display them in
- frequency range

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The analyzer is adjusted to measure return loss \( S_{11} \) on channel 1 and display as log magnitude.
- The analyzer is adjusted to measure return loss \( S_{11} \) on channel 2 and display the phase.
- The dual-channel display mode is activated.
- The system operator is prompted to enter the frequency range of the measurement.
- The displays are autoscaled.
- The system operator is prompted to press “Enter” on the computer keyboard to view four types of measurements simultaneously.
- Channels 3 and 4 are turned on.
- Channel 2 is adjusted to measure transmission \( S_{21} \) displayed in log magnitude, and then the display is autoscaled.
- Channel 3 is adjusted to measure reflected power \( A \) displayed in log magnitude, and then the display is autoscaled.
- Channel 4 is adjusted to measure transmitted power \( B \) displayed in log magnitude, and then the display is autoscaled.
- The four channels are each displayed in a separate graticule.
- The analyzer is released from remote control and the program ends.
BASIC Program Listing

This program demonstrates setup of various measurement parameters such as start frequency, stop frequency, etc. The program first selects one type of measurement to be viewed using dual-channel display format. The specified start and stop frequencies are then programmed and the analyzer display is autoscaled. The program concludes by displaying four types of measurements simultaneously.

`ASSIGN @Nwa TO 716  ! Assign an I/O path for the analyzer`

`CLEAR SCREEN  ! Generate an IFC (Interface Clear)`

`CLEAR @Nwa  ! SDC (Selected Device Clear) analyzer`

Example 1B: Verifying Parameters

This example shows how to read analyzer settings into your controller. Appending a “?” to a command that sets an analyzer parameter will return the value of that setting. Parameters that are set as ON or OFF when queried will return a zero (0) if off or a one (1) if active. Parameters are returned in ASCII format, FORM 4. This format varies in length from 1 to 24 characters-per-value. In the case of marker or other multiple responses, the values are separated by commas.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The number of points in the trace is queried and dumped to a printer.
- The start frequency is queried and output to a printer.
- The averaging is queried and output to a printer.
- The analyzer is released from remote control and the program ends.

Running the Program

The analyzer is preset. The preset values are returned and printed out for: the number of points, the start frequency, and the state of the averaging function. The analyzer is released from remote control and the program ends.

BASIC Program Listing

```
10 ! This program performs some example queries
20 ! of network analyzer settings. The number of
30 ! points in a trace, the start frequency
40 ! and if averaging is turned on, are determined and displayed.

Measurement Calibration Examples

This section shows you how to coordinate a measurement calibration over GPIB. You can use the following sequence for performing either a manual measurement calibration, or a remote measurement calibration via GPIB:

1. Select the calibration type.
2. Measure the calibration standards.
3. Declare the calibration done.

The actual sequence depends on the calibration kit and changes slightly for 2-port calibrations, which are divided into three calibration sub-sequences. The following examples are included:

- Example 2A is a program designed to perform a response calibration.
- Example 2B is a program designed to perform a 1-port measurement calibration.
- Example 2C is a program designed to perform an enhanced response calibration.
- Example 2D is a program designed to perform a full 2-port measurement calibration. (For use with ES models only.)
- Example 2E is a program designed to accurately measure a “non-insertable” 2-port device, using adapter removal. (For use with ES models only.)
- Example 2F is a program designed to use raw data to create a calibration, sometimes called Simmcal. (For use with ES models only.)
- Example 2G is a program designed to offload the calculation of the 2-port error corrected data to an external computer. (For use with ES models only.)

Example programs 2A through 2D illustrate how to perform different types of calibrations using any of the following calibration kits:

<table>
<thead>
<tr>
<th>Network Analyzer</th>
<th>Calibration Kits</th>
</tr>
</thead>
<tbody>
<tr>
<td>8753ET/ES</td>
<td>85031B (7-mm)</td>
</tr>
<tr>
<td></td>
<td>85032B/E (type-N 50 Ω)</td>
</tr>
<tr>
<td>8720E series analyzers</td>
<td>85052B/D (3.5-mm)</td>
</tr>
<tr>
<td></td>
<td>85056A/D (2.4-mm)</td>
</tr>
</tbody>
</table>

If you wish to use a different calibration kit, modify the example program accordingly. These programs simplify the calibration by providing explicit directions on the analyzer display while allowing the user to run the program from the controller keyboard. More information on selecting calibration standards can be found in your analyzer’s user’s guide.
NOTE For type-N connectors, the sex of the connector that the calibration standard will mate to must be observed. These programs assume that the connector on PORT 1 (REFLECTION port on ET models) is a female test port and that PORT 2 (TRANSMISSION port on ET models) is a male test port.

Calibration Kits

The calibration kit tells the analyzer what standards to expect at each step of the calibration. The set of standards associated with a given calibration is termed a “class.” For example, measuring the short during a 1-port measurement calibration is one calibration step. All of the shorts that can be used for this calibration step make up the class, which is called class S11B. For the 7-mm and the 3.5-mm cal kits, class S11B uses only one standard. For type-N cal kits, class S11B contains two standards: male and female shorts.

When doing a 1-port measurement calibration using a 7- or 3.5-mm calibration kit, selecting SHORT automatically measures the short because the class contains only one standard. When doing the same calibration in type-N, selecting SHORT brings up a second menu, allowing the operator to select which standard in the class is to be measured. The sex listed refers to the test port: if the test port is female, then the operator selects the female short option. Once the standard has been selected and measured, the DONE key must be pressed to exit the class.

Doing a 1-port measurement calibration over GPIB is very similar. When using a 7- or 3.5-mm calibration kit, sending CLASS11B will automatically measure the short. In type-N, sending CLASS11B brings up the menu with the male and female short options. To select a standard, use STANA or STANB. The STAN command is appended with the letters A through G, corresponding to the standards listed under softkeys 1 through 7, softkey 1 being the topmost softkey.

The STAN command is OPC-compatible. A command that calls a class is only OPC-compatible if that class has only one standard in it. If there is more than one standard in a class, the command that calls the class brings up another menu, and there is no need to query it. DONE; must be sent to exit the class.

Example 2A: Response Calibration

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The appropriate calibration kit is selected.
- The softkey menu is deactivated.
- The response calibration sequence is run.
- The response calibration data is saved.
- The softkey menu is activated.
- The analyzer is released from remote control and the program ends.
Running the Program

NOTE This program does not modify the instrument state in any way. Before running the program, set up the desired instrument state.

The program assumes that the test ports have a 7-mm, type-N 50 Ω, 3.5-mm, or 2.4-mm interface or an adapter set using a 7-mm, type-N 50 Ω, 3.5-mm, or 2.4-mm interface. The prompts appear just above the message line on the analyzer display. Pressing Enter on the controller keyboard continues the program and measures the standard. The program will display a message when the measurement calibration is complete.

BASIC Program Listing

10 ! This program guides the operator through a response calibration
20 ! using a thru (cable). The operator must choose from one of the
30 ! following calibration kits:
40 !
50 ! Analyzer Cal Kits
60 ! -------- --------

Example 2C: Enhanced Response Calibration

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The appropriate calibration kit is selected.
- The softkey menu is deactivated.
- The enhanced response calibration sequence is run.
- The enhanced response calibration data is saved.
- The softkey menu is activated.
- The analyzer is released from remote control and the program ends.

Running the Program

NOTE This program does not modify the instrument state in any way. Before running the program, set up the desired instrument state.

The program assumes that the test ports have a 7-mm, type-N 50 Ω, 3.5-mm, or 2.4-mm interface or an adapter set using a 7-mm, type-N 50 Ω, 3.5-mm, or 2.4-mm interface. The prompts appear just above the message line on the analyzer display. Pressing (Enter) on the controller keyboard continues the program and measures the standard. The program will display a message when the measurement calibration is complete.

**Example 2D: Full 2-Port Measurement Calibration**

**NOTE** This program is only valid on ES model analyzers.

A full 2-port calibration removes both the forward- and reverse-error terms so that all four S-parameters of the device under test can be measured.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The appropriate calibration kit is selected.
- The softkey menu is deactivated.
- The 2-port calibration sequence is run.
- The operator is prompted to choose or skip the isolation calibration.
- The softkey menu is activated.
- The analyzer is released from remote control and the program ends.

**Running the Program**

**NOTE** This program does not modify the instrument state in any way. Before running the program, set up the desired instrument state.

The program assumes that the test ports have either a 7-mm or 3.5-mm interface or an adapter set using either a 7-mm or 3.5-mm interface. The prompts appear just above the message line on the analyzer display. After the prompt is displayed, pressing **Enter** on the computer console continues the program and measures the standard. The operator has the option of omitting the isolation calibration. If the isolation calibration is performed, averaging is automatically employed to ensure a good calibration. The program will display a message when the measurement calibration is complete.
BASIC Program Listing

Example 2E: Adapter Removal Calibration

NOTE
This program is only valid on ES model analyzers.

This program shows how to accurately measure a “non-insertable” 2-port device. A device is termed “non-insertable” if its connectors do not match those of the analyzer front panel. More information on the adapter removal technique can be found in your analyzer’s user’s guide.

The following is an outline of the program’s processing sequence:

• An I/O path is assigned for the analyzer.
• The system is initialized.
• The internal disk is selected as the active storage device.
• The system operator is prompted for the name of the instrument state file which has a 2-port calibration performed for Port 1’s connector.
• The calibration arrays for Port 1 are recalled from the corresponding disk file.
• The system operator is prompted for the known electrical delay value of the adapter.
• The new calibration coefficients, with the effects of the adapter removed, are computed by the analyzer using the adapter delay in conjunction with the calibration arrays for both ports.
• The analyzer is released from remote control and the program ends.

CAUTION
Do not mistake the line switch for the disk eject button. If the line switch is mistakenly pushed, the instrument will be turned off, losing all settings and data that have not been saved.

Running the Program

The analyzer is initialized and the internal disk drive is selected. The operator is queried for the name of the instrument state file having a 2-port calibration performed for Port 1’s connector. The calibration arrays for Port 1 are recalled from the corresponding disk file. The system operator is prompted for the name of the instrument state file having a 2-port calibration performed for Port 2’s connector. The calibration arrays for Port 2 are recalled from the corresponding disk file. The system operator is prompted for the known electrical delay of the adapter and this value is written to the analyzer. The calibration coefficients with adapter effects removed are computed and the program ends.

Example 2F: Using Raw Data to Create a Calibration (Simmcal)

NOTE This program is only valid on ES model analyzers.

This program simulates a full 2-port cal by measuring the raw data for each “standard” and then loading it later into the appropriate arrays. The program can be adapted to create additional calibrations using the same arrays. It uses the analyzer’s default 7-mm cal kit.

CAUTION This feature is not currently supported with TRL calibrations.

The following is an outline of the programs' processing sequence:

• An I/O path is assigned for the analyzer.
• The system is initiated.
• The instrument ID is queried so that the program can later branch accordingly for the S11C and S22C (load) classes.
• The number of points is set to correspond to the size of the dimensioned memory arrays and ASCII data format is selected.
• The 7-mm calibration kit is selected, sweep time is set to 1 second, and the analyzer is placed into hold mode.
• S11 measurement is selected for gathering the forward reflection standards.
• The system operator is prompted to connect each of the three standards, one at a time.
• Following each prompt, a single sweep is taken and the raw measured data for that standard is read from the analyzer into a corresponding memory array in the controller.
• S22 measurement is selected for gathering the reverse reflection standards.
• The system operator is prompted in the same manner as before and the raw data for the three standards is measured and stored away as before.
• The system operator is prompted to make the thru connection between Port 1 and Port 2.
• S21 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to forward transmission.
• S11 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to forward thru match.
• S12 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to reverse transmission.
• S22 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to reverse thru match.
• The analyzer begins the normal 2-port calibration procedure, but with the default beep turned off.
• A single sweep is taken for the measurement of each standard to provide “dummy” data,
which is immediately replaced with the previously measured raw data from the array corresponding to that measurement.

- The analyzer uses the raw data to compute the error coefficients and is placed back into continuous sweep mode.
- The analyzer is released from remote control and the program ends.

**Running the Program**

The system is initialized, the number of points is set to 51, and the 7-mm calibration kit is selected. Sweep time is set to 1 second and the analyzer is placed into hold mode.

The S11 measurement is selected and the system operator is prompted to connect each of the three forward reflection standards, one at a time. Following each prompt, a single sweep is taken, which concludes with a beep from the external controller.

The S22 measurement is selected for gathering the reverse reflection standards. The system operator is prompted in the same manner as before and the three standards are measured as before.

The system operator is prompted to make the thru connection between Port 1 and Port 2. A single sweep is taken for each of the four S-parameters, each concluding with a beep.

The analyzer begins the normal 2-port calibration procedure, but with the default beep turned off. A single sweep is taken for each measurement of each standard, providing “dummy” data which is immediately replaced with the data from the array corresponding to that measurement. The analyzer computes the error correction coefficients and is placed back into continuous sweep mode. The default beep is re-enabled and the program ends.

**BASIC Program Listing**

```basic
10 ! This program simulates a full 2-port cal by first getting the
20 ! raw data for each “standard” and then loading it into the
30 ! appropriate arrays later. For simplicity, this is done with
40 ! ASCII format, 51 points, and the 7mm calibration kit. This also
50 ! simplifies the input of the standards because there is only one
60 ! standard associated with each particular class in the 7mm cal kit,
70 ! except for the S11C/S22C classes on the 8719/8720/8722. The
80 ! program queries the analyzer model number and deals with the
90 ! S11C/S22C classes accordingly.

Example 2G: Take4 — Error Correction Processed on an External PC

NOTE This program is only valid on ES model analyzers.

Take4 mode offloads the error correction process to an external PC in order to increase throughput on the analyzer.

When using the analyzer with error correction turned off, it will only sweep in one direction, collecting data for the parameter selected under the (Meas) key. To emulate the error correction process in an external computer, you collect the raw data for each of the four S-parameters.

Take4 initiates a mode in which every measurement cycle is characterized by sweeping in both the forward and reverse directions and collecting raw data for all four S-parameters. Using previously extracted calibration arrays, you can then extract the raw data (or the pre-raw data, as explained later in this section) for the S-parameters and perform the error correction in an external computer. When measuring more than one parameter, this process can be done in less time than if using the normal instrument error correction and data transfer (see Table 7-9 on page 7-50).

NOTE This mode is intended for remote use only. Any attempt to change the measured parameter or any attempt to apply a calibration will turn off the Take4 mode. The displayed trace data is always uncorrected S11, regardless of what the display may indicate.

Using the Take4 mode requires the following steps:

**Manual steps:**

1. Set up the measurement state.

2. Turn off raw offsets by selecting (System) **CONFIGURE MENU RAW OFFSET OFF**. This selection achieves two things:
   - Eliminates attenuator offsets and sampler hardware offsets from the cal arrays, which are generated in the 2-port error correction. This makes the cal arrays and the eventual OUTPPRE arrays compatible, both using pre-raw data.
   - Eliminates sampler correction, a frequency response correction that is normally contained in pre-raw data. This is done because sampler correction is not needed for data that will be fully corrected, and because instrument states recall faster without it. To realize this efficiency, you must also disable spur avoidance (see next step).

3. Optional step: Turn off spur avoidance by selecting (System) **CONFIGURE MENU SPUR AVOID OFF**. Spur avoidance creates a table of values as part of the sampler offset table. The creation of this table takes considerable time during a recall of an instrument state. Turning off spur avoidance will save time during frequency changes and instrument state recalls.

4. Perform a 2-port error correction and save it to a register.
5. Connect the device under test (DUT).

The instrument is now configured for the program to read the correction arrays and apply the Take4 mode.

**Programming steps:**

6. Extract the twelve calibration arrays using the commands OUTPCALC[01-12].

7. Enable Take4 mode using the command TAKE4ON.

8. Take a sweep and extract the four pre-raw or raw arrays.

   • To extract pre-raw data arrays (see previous discussion on raw offsets), you can use the commands SWPSTART (initiate a single sweep) with OUTPPRE[1-4]. These commands are more efficient than SING and OUTPRAF[1-4] because the analyzer will respond to OUTPPRE1 and OUTPPRE2 as soon as the forward sweep is done and transfer the data during the reverse sweep. With SING, the GPIB bus is held off until the entire sweep is complete.

   • To extract raw data arrays, you can use the commands SING (initiate a single sweep) with OUTPRAW[1-4], or the slightly faster OUTPRAF[1-4]. If the cal arrays were created using **RAW OFFSET ON**, you should use this method so that your measurement data is compatible with the calibration data.

9. Apply the calibration arrays (see **Table 3-3 on page 3-19**) to either the pre-raw or raw data as described in programming example 2G and in the user's guide (see the figure titled “Full 2-Port Error Model”).

Take4 mode used in conjunction with an HP Omnibook 5500CT laptop, 133 MHz Pentium, running HP VEE 4.0 as program language.

Programming example 2G is the complete execution of a two port error correction offloaded to an external PC.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer. Binary mode is used for data transfers in order to get the fastest response.
- The system is initialized.
- The state of raw offsets is queried and turned off if they had been on.
- The analyzer is placed into local mode and the system operator is prompted to set up a 2-port calibration before continuing.
- The calibration coefficients are read from the analyzer into memory arrays.
- The calibration is turned off and the analyzer is placed into TAKE4 mode and HOLD mode.
- The operator is prompted to connect the DUT and select which S-parameter to send back to the analyzer.
- The currently displayed data is saved to the analyzer's internal memory to initialize the memory array.
- The analyzer is set up to display memory only and the default beep is turned off.
- The operator is prompted to press any key to terminate the program.
- A sweep is initiated and the main loop of the program begins.
- After the sweep concludes, the four pre-raw S-parameters are read from the analyzer into an array in the computer.
• The error-corrected (calibrated) S-parameters are calculated using the pre-raw data and calibration coefficients.

• The calibrated data for the S-parameter selected earlier is sent into the analyzer and saved to the analyzer's internal memory.

• A new sweep is initiated and the loop repeats if there has been no keyboard activity.

• Upon exit of the loop, the analyzer is set up to display the active measurement trace.

• The analyzer's internal calibration is turned back on and continuous sweep mode is resumed.

• The analyzer is released from remote control and the program ends.

### Running the Program

The analyzer is initialized and raw offsets are turned off. After the analyzer is placed in local mode, the operator is prompted to set up a 2-port calibration before continuing. The resulting calibration coefficients are read from the analyzer into memory arrays.

Next, the calibration is turned off and the analyzer is placed into TAKE4 mode and HOLD mode. After being prompted to connect the DUT, the operator selects which S-parameter to send back to the analyzer. The currently displayed data is saved to the analyzer's internal memory and the analyzer is set up to display memory only. The operator is prompted to press any key to terminate the program, a sweep is initiated and the main loop of the program begins.

After the sweep concludes, the four pre-raw S-parameters are read from the analyzer into memory arrays. The error-corrected (calibrated) S-parameters are calculated and the calibrated data for the S-parameter selected earlier is read into the analyzer and saved to the analyzer's internal memory. A new sweep is initiated and the loop repeats if there has been no keyboard activity.

Upon exit of the loop, the analyzer is set up to display the active measurement trace. The analyzer's internal calibration is turned back on and continuous sweep mode is resumed before the program ends.

### BASIC Program Listing

```
1 ! This program demonstrates the TAKE4 mode.
2 ! The program first asks the user to set up the instrument
3 ! with a 2-port calibration. The subroutine “Read_Cal_co”
4 ! is used to read the 12 term error correction arrays into
5 ! a (N x 12) 2-dimension array (N = number of points). This will
6 ! be used in the “Calc_2_port” subroutine. The program turns off
7 ! error correction, puts the analyzer in hold, turns on TAKE4
8 ! mode, and starts a sweep. The subroutine “Read_4_raw” reads in
9 ! the uncorrected data. The subroutine “Calc_2_port” calculates
10 ! the error correction and returns the corrected arrays.
11 ! The corrected S-parameter is re-input to the analyzer, stored
12 ! in the memory trace and displayed in memory for a visual
13 ! indication of the take4 function.

Measurement Data Transfer Examples

There are two methods that can be used to read trace information from the analyzer:

- selectively, using the trace markers
- completely, using the trace-data array

If only specific information (such as a single point on the trace or the result of a marker search) is required, the marker output command can be used to read the information. If all of the trace data is required, see Examples 3B through 3E for examples of the various formats available.

Trace-Data Formats and Transfers

Refer to Table 7-10 on page 59. This table shows the number of bytes required to transfer a 201-point trace in the different formats. As you will see in the first example (FORM 4), ASCII data is the easiest to transfer, but the most time consuming due to the number of bytes in the trace. If you are using a PC-based controller, a more suitable format would be FORM 5. To use any trace data format other than FORM 4 (ASCII data) requires some care in transferring the data to the computer. Data types must be matched to read the bytes from the analyzer directly into the variable array. The computer must be told to stop formatting the incoming data and treat it as a binary-data transfer. All of the binary data formats also have a four-byte header to deal with. The first two bytes are the ASCII characters “#A” that indicate that a fixed length block transfer follows, and the next two bytes form an integer containing the number of bytes in the block to follow. The header must be read in to separate it from the rest of the block data that is to be mapped into an array. “Array-Data Formats” on page 4-6 discusses the different types of formats and their compositions.

Data may also be transferred from several different locations in the trace-processing chain. These examples will illustrate formatted-data transfers, but other locations in the trace-data processing chains may be accessed. See Figure 5-1 on page 5-3.

In this section, an example of each of the data formats will be shown for comparison. In general, FORM 1 (internal binary format) should be used for traces that are not being utilized for data content. Calibration data that is being transferred to a file and back is a good example. See “Example 3D: Data Transfer Using Frequency-Array Information” on page 7-64.

Arrays which will be interpreted or processed within your program should be in FORM 2, 3 or 5, whichever is appropriate for your computer. Example 3C shows how to transfer a trace in these formats.

In Examples 3B and 3C, the frequency counterpart of each data point in the array is also determined. Many applications generate a frequency and magnitude, or a phase array for the test results. Such data may be required for other data processing applications (such as comparing data from other measurements).

In Example 3B, the frequency data is constructed from the frequency span information. Alternatively, it is possible to read the frequencies directly out of the instrument with the OUTPLIML command. OUTPLIML reports the limit-test results by transmitting the stimulus
point tested, a number indicating the limit-test results, and then the upper and lower limits at that stimulus point (if available). The number indicating the limit results is a -1 for no test, 0 for fail, and 1 for pass. If there are no limits available, the analyzer transmits zeros. For this example, we delete the limit test information and keep the stimulus information.

In Example 3C, the limit-test array is read into the controller and used to provide the values directly from the analyzer memory. Reading from the limit-test array is convenient, although it outputs the results in ASCII format (form 4), which may be slow. If there is no other way to obtain the frequency data, this transfer time may be acceptable. Frequency information becomes more difficult to determine when not using the linear sweep mode. Log-frequency sweeps and list-frequency sweeps have quite different values for each data point. For these special cases, the additional time spent reading out the limit test results is an acceptable solution for obtaining the valid frequency information for each data point in the trace.

**Example 3A: Data Transfer Using Markers**

Markers are the simplest form of trace-data transfer. A marker may be positioned using one of three methods:

- by a frequency location
- by an actual data point location
- by a trace-data value

In the following example, the marker is positioned on the trace's maximum value. Once positioned on the trace, the trace data at that point can be read into the controller. The marker data is always returned in FORM 4, ASCII format. Each number is sent as a 24-character string. Characters can be digits, signs, or decimal points. All characters should be separated by commas. In the case of markers, three numbers are sent. The display format determines the values of the marker responses. See Table 4-1 on page 4-5.

When using trace data, it is important to control the network analyzer's sweep function (and therefore the trace data) from the computer. Using the computer to control the instrument's sweep ensures that the data you read into the controller is in a quiescent or steady state. It also ensures that the measurement is complete.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The selected frequency span is swept once.
- The marker is activated and placed on the maximum trace value.
- The three marker values are output to the controller and displayed.
- The instrument is returned to local control and the program ends.
Running the Program

Run the program. The analyzer is preset and a sweep is taken. Marker 1 is enabled and positioned on the largest value in the trace. The marker is output to the controller and printed on the controller display. The analyzer is returned to local control. Position the marker using the front panel knob or data-entry keys, and compare the displayed value on the analyzer with the value that was transmitted to the controller.

The three values returned to the controller are:
1. reflection, in dB
2. a non-significant value
3. the stimulus frequency at the maximum point

A non-significant value means that the analyzer returned a value that is meaningless in this data format.

Table 4-1 on page 4-5 provides an easy reference for the types of data returned with the various data-format operational modes.

*No header is used in FORM 4.

The next most common data transfer is to transfer a trace array from the analyzer. Table 7-10 shows the relationship of the two values-per-point that are transferred to the analyzer. When FORM 4 is used, each number is sent as a 24-character string, each character represented by a digit, sign, or decimal point. Each number is separated from the previous number with a comma. Since there are two numbers-per-point, a 201-point transfer in FORM 4 takes 10,050 bytes. This form is useful only when input-data formatting is difficult with the instrument controller. Refer to Table 7-10 for a comparison with the other formats.

An example of a simple data transfer using FORM 4 (ASCII data transfer) is shown in this program. A fairly common requirement is to create frequency-amplitude data pairs from the trace data. No frequency information is included with the trace data transfer, because the frequency data must be calculated. Relating the data from a linear frequency sweep to frequency can be done by querying the analyzer start frequency, the frequency span, and the number of points in the sweep. Given that information, the frequency of point N in a linear frequency sweep is:

\[ F = \text{StartFrequency} + (N - 1) \times \frac{\text{Span}}{(\text{Points} - 1)} \]

Example 3B illustrates this technique. It is a straight-forward solution for linear uniform sweeps. For other sweep types, frequency data is more difficult to construct and may best be read directly from the analyzer’s limit-test array. See “Example 3D: Data Transfer Using Frequency-Array Information” on page 7-64.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
Programming Examples
Measurement Data Transfer Examples

- The trace-data array is allocated.
- The trace length is set to 11.
- The selected frequency span is swept once.
- The FORM 4, ASCII format is set.
- The formatted trace is read from the analyzer and displayed.
- The frequency increments between the points are calculated.
- The marker is activated and placed at the lowest frequency of the analyzer (50 MHz).
- The instrument is returned to local control and the program ends.

Running the Program

Run the program and watch the controller console. The analyzer will perform an instrument preset. The program will then print out the data values received from the analyzer. The marker is activated and placed at the left-hand edge of the analyzer's display. Position the marker with the knob and compare the values read with the active marker with the results printed on the controller console. The data points should agree exactly. Keep in mind that no matter how many digits are displayed, the analyzer is specified to measure:

- magnitude to a resolution of 0.001 dB
- phase to a resolution of 0.01 degrees
- group delay to a resolution of 0.01 ps

Changing the display format will change the data sent with the OUTPFORM transfer. See Table 7-10 for a list of the specific data that is provided with each format. The data from OUTPFORM reflects all the post processing such as:

- time domain
- gating
- electrical delay
- trace math
- smoothing

Example 3C: Data Transfer Using Floating-Point Numbers

This example program illustrates data transfer using FORM 3 in which data is transmitted in the floating-point formats. FORM 2 is nearly identical except for the IEEE 32-bit format of 4 bytes-per-value. FORM 5 reverses the order of the bytes to conform with the PC conventions for defining a real number.

The block-data formats have a four-byte header. The first two bytes are the ASCII characters “#A” that indicate that a fixed-length block transfer follows, and the next two bytes form an integer containing the number of bytes in the block to follow. The header must be read in so that data order is maintained.

This transfer is more than twice as fast than a FORM 4 transfer. With the FORM 4 transfer, 10,050 bytes are sent (201 points × 2 values-per-point × 24 bytes-per-value). Using FORM 2 to transfer the data, only 1612 bytes are sent (201 points × 2 values-per-point × 4 bytes-per-value). See “Array-Data Formats” on page 4-6.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The integer variables are defined to contain the header information.
- The number of points in the trace is set to 11.
- The selected frequency span is swept once.
- Data-transfer format 3 is set.
- The headers are read from the trace.
- The array size is calculated and allocated.
- The trace data is read in and printed.
- The marker is activated and placed at the lowest frequency of the analyzer (50 MHz).
- The instrument is returned to local control and the program ends.

Running the Program

Run the program. The computer displays the number of elements and bytes associated with the transfer of the trace, as well as the first 10 data points. Position the marker and examine the data values. Compare the displayed values with the analyzer's marker values.

Example 3D: Data Transfer Using Frequency-Array Information

Example 3C was used to read in the trace-data array. Example 3D explains how to use the limit-test array to read the corresponding frequency values for the completed trace array into the controller. The analyzer is set to sweep from 50 MHz to 200 MHz in log-frequency mode with the number of points in the trace set to 11. This makes it very difficult to compute the frequency-point spacing in the trace. The points are equally spaced across the trace, but not equally spaced in relation to frequency (because the frequency span is displayed in a logarithmic scale, as opposed to a linear scale). The limit-test data array may be read from the analyzer to provide the frequency values for each data point. Four values are read for each data point on the analyzer. The test results and limit values are not used in this example. Only the frequency values are used. This technique is an effective method of obtaining the non-linear frequency data from the analyzer display. The test data and frequencies are printed on the controller display and the marker is enabled to allow the operator to examine the actual locations on the analyzer display.

The following is an outline of the program's processing sequence:

• An I/O path is assigned for the analyzer.
• The system is initialized.
• The integer variables for the header information are defined.
• The number of points in the trace is set to 11.
• The frequency span (50 MHz to 200 MHz) is selected.
• The log-frequency sweep is selected.
• The data-transfer format 3 is set.
• The headers are read from the trace.
• The array size is calculated and allocated.
• The trace data is read in.
• The limit-test array is calculated and allocated.
• The limit-line test array is read in.
• The table header is printed.
• The program cycles through the trace values.
• The trace data and frequency are printed.
• The discrete-marker mode is activated.
• The marker is activated and placed at the lowest frequency of the analyzer (50 MHz).
• The instrument is returned to local control and the program ends.

Running the Program

Run the program. Observe the controller display. The corresponding frequency values are shown with the trace-data values. Position the marker and observe the relationship between the frequency values and the point spacing on the trace. Compare the trace-data values on the analyzer with those shown on the controller display.

Example 3E: Data Transfer Using FORM 1 (Internal-Binary Format)

FORM 1 is used for rapid I/O transfer of analyzer data. It contains the least number of bytes-per-trace and does not require re-formatting in the analyzer. This format is more difficult to convert into a numeric array in the controller.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The integer variables for the header information are defined.
- The string variable for the header is defined.
- The selected frequency span is swept once.
- The internal-binary format is selected.
- The error-corrected data is output from the analyzer.
- The two data-header characters and the two length bytes are read in.
- The string buffer is allocated for data.
- The trace data is read into the string buffer.
- The analyzer is restored to continuous-sweep mode and queried for command completion.
- The instrument is returned to local control and the program ends.

Running the Program

The analyzer is initialized. The header and the number of bytes in the block transfer are printed on the controller display. Once the transfer is complete, the number of bytes in the data string is printed. Compare the two numbers to be sure that the transfer was completed.

BASIC Program Listing

Measurement Process Synchronization Examples

**Figure 7-1 Status Reporting Structure**

Status Reporting

The analyzer has a status reporting mechanism, illustrated in Figure 7-1, that provides information about specific analyzer functions and events. The status byte is an 8-bit register with each bit summarizing the state of one aspect of the instrument. For example, the error queue summary bit will always be set if there are any errors in the queue. The value of the status byte can be read with the GPIB serial poll operation. This command does not automatically put the instrument in remote mode, which gives you access to the analyzer front-panel functions. The status byte can also be read by sending the command `OUTPSTAT`. Reading the status byte does not affect its value.
The status byte summarizes the error queue, as mentioned before. It also summarizes two event-status registers that monitor specific conditions inside the instrument. The status byte also has a bit (6) that is set when the instrument is issuing a service request over GPIB, and a bit (0) that is set in the event-status register when the analyzer has data to send out over GPIB. See “Status Reporting” on page 6-3 for a discussion of the event-status registers.

**Example 4A: Using the Error Queue**

The error queue holds up to 20 instrument errors and warnings in the order that they occurred. Each time the analyzer detects an error condition, the analyzer displays a message, and puts the error in the error queue. If there are any errors in the queue, bit 3 of the status byte will be set. The errors can be read from the queue with the **OUTPERRO** command. **OUTPERRO** causes the analyzer to transmit the error number and message of the oldest error in the queue.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The error-message string is allocated.
- The analyzer is released from remote control.
- The program begins an endless loop to read the error queue.
- The status byte is read with a serial poll.
- The program tests to see if an error is present in the queue.
- The error-queue bit is set.
- The program requests the content of the error queue.
- The error number and string are read.
- The error messages are printed until there are no more errors in the queue.
- The instrument is returned to local control.
- The controller emits a beep to attract the attention of the operator and resumes searching for errors.

**Running the Program**

Run the program. The analyzer goes through the preset cycle. Nothing will happen at first. The program is waiting for an error condition to activate the error queue. To cause an error, press a blank softkey. The message **CAUTION: INVALID KEY** will appear on the analyzer. The computer will beep and print out two error messages. The first line will be the invalid key error message, and the second line will be the **NO ERRORS** message. To clear the error queue, you can either loop until the **NO ERRORS** message is received, or wait until the bit in the status register is cleared. In this case, we wait until the status bit in the status register is clear. Note that while the program is running, the analyzer remains in the local mode and the front-panel keys may be accessed.
The error queue will hold up to 20 errors until all the errors are read out or the instrument is preset. It is important to clear the error queue whenever errors are detected. Otherwise, old errors may be mistakenly associated with the current instrument state.

Press [System] and then the unlabeled key several times quickly and watch the display. The number of errors observed should correspond to the number of times you pressed the key.

As another example, press [Cal] [CORRECTION ON]. A complete list of error messages and their descriptions can be found in your analyzer’s reference guide.

The program is in an infinite loop waiting for errors to occur. End the program by pressing [Reset] or [Break] on the controller keyboard.

NOTE Not all messages displayed by the analyzer are put in the error queue: operator prompts and cautions are not included.

**BASIC Program Listing**

```basic

```
Example 4B: Generating Interrupts

It is also possible to generate interrupts using the status-reporting mechanism. The status-byte bits can be enabled to generate a service request (SRQ) when set. In turn, the instrument controller can be set up to generate an interrupt on the SRQ and respond to the condition which caused the SRQ.

To generate an SRQ, a bit in the status byte is enabled using the command \texttt{SRE} \textsubscript{n}. A one (1) in a bit position enables that bit in the status byte. Hence, \texttt{SRE} 8 enables an SRQ on bit 3, the check-error queue, since the decimal value 8 equals 00001000 in binary representation. Whenever an error is put into the error queue and bit 3 is set, the SRQ line is asserted, illuminating the (S) indicator in the GPIB status block on the front panel of the analyzer. The only way to clear the SRQ is to disable bit 3, re-enable bit 3, or read out all the errors from the queue.

A bit in the event-status register can be enabled so that it is summarized by bit 5 of the status byte. If any enabled bit in the event-status register is set, bit 5 of the status byte will also be set. For example \texttt{ESE} 66 enables bits 1 and 6 of the event-status register, since in binary, the decimal number 66 equals 01000010. Hence, whenever active control is requested or a front-panel key is pressed, bit 5 of the status byte will be set. Similarly, \texttt{ESNB} \textsubscript{n} enables bits in event-status register B so that they will be summarized by bit 2 in the status byte.

To generate an SRQ from an event-status register, enable the desired event-status register bit. Then enable the status byte to generate an SRQ. For instance, \texttt{ESE} 32; \texttt{SRE} 32; enables the syntax-error bit. When the syntax-error bit is set, the summary bit in the status byte will be set. This will, in turn, enable an SRQ on bit 5 of the status byte, the summary bit for the event-status register.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The status registers are cleared.
- The event-status register bit 5 is enabled.
- The status-register bit 5 is enabled.
- The interrupt pointer is enabled and points to a subroutine.
- Two bad commands are sent to the analyzer to generate errors.
- The controller reads a serial-poll byte from GPIB in the event of an interrupt.
- The program tests for an SRQ.
- If the SRQ is not generated by the analyzer, the subroutine stops and displays \texttt{SRQ FROM OTHER DEVICE}.
- If the SRQ was generated by the analyzer, the program reads the status byte and event-status register.
- If bit 5 in the event-status register is set, the program prints: \texttt{SYNTAX ERROR FROM ANALYZER}. 
• If bit 5 in the event-status register is not set, the program prints: **SYNTAX ERROR BIT NOT SET.**

• The SRQ interrupt is re-enabled on the bus.

• At the finish, the interrupt is deactivated.

• The analyzer is released from remote control and the program ends.

**Running the Program**

Run the program. The computer will preset the analyzer, then pause for a second or two. After pausing, the program sends an invalid command string “**STIP 2 GHZ;**” to cause a syntax error. This command is intended to be “**STOP 2 GHZ;**”. The computer will display a series of messages from the SRQ-handler routine. The analyzer will display **CAUTION: SYNTAX ERROR** and the incorrect command, pointing to the first character it did not understand.

The SRQ can be cleared by reading the event-status register and clearing the latched bit, or by clearing the enable registers with **CLES**. The syntax-error message on the analyzer display can only be cleared by the GPIB Device Clear (DCL) message or Selected Device Clear (SDC) message. Device Clear is not commonly used because it clears every device on the bus. Selected Device Clear can be used to reset the input and output queue and the registers of a specific instrument on the bus. This will also clear all the interrupt definitions.

**BASIC Program Listing**

```basic
10 ! This program is an example of using an SRQ based interrupt to detect an error condition in the analyzer. In this example, a syntax error is generated with an invalid command. The status byte is read in and tested. The error queue is read, printed out and then cleared.

Example 4C: Power Meter Calibration

NOTE This example program will not work with HP BASIC for Windows.

For increased accuracy of the analyzer’s PORT 1-output power, a power meter calibration is available. This measurement-accuracy enhancement technique is described in your analyzer’s user’s guide. The example described will perform the sample and sweep calibration under GPIB remote control.

The power meter is usually connected to PORT 1 for the forward measurements. Its address must be set correctly and it must be connected to the GPIB. The power meter address can be set by pressing: \text{[Local SET ADDRESSES \ ADDRESS P MTR/GPIB]} and using the \text{[ ]} keys or the numeric key pad to complete the process. The appropriate command must be selected for the model number of power meter being used. Press \text{[POWER MTR: [ ]]} until the model being used is displayed between the brackets.

The correction factors for the power sensor are entered into the analyzer. All of these steps are explained in your analyzer’s user’s guide.

The number of readings-per-point must also be selected before starting. The number of points directly affects the measurement time of the calibration sequence. The power meter must be triggered and read by the analyzer for each trace point. Typically, two readings-per-point is considered appropriate. More than two readings-per-point could lead to unacceptable processing time.

To control a power meter calibration via GPIB, the analyzer must be set to pass-control mode. The analyzer must step to the next point in the sweep and read the power present at the power meter sensor. For this operation to take place, the system controller must set up the measurement and then pass control to the analyzer to read each data point in the sweep. After reading the data point from the power meter, the analyzer passes control back to the system controller. The analyzer then sets up to measure the next point and again requests control from the system controller. This process continues until the analyzer signals that the entire sweep has been measured point-by-point.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The number of points in the trace is set.
- The number of readings-per-point is set.
- The frequency span is set.
NOTE

The frequency span of this example program may need to be modified in order to correspond to the frequency ranges of your analyzer.

- The reference channel is measured.
- The power meter calibration array is allocated.
- The power meter model is chosen.
- The status registers are cleared.
- The request-control summary bit is enabled.
- The pass-control mode is enabled.
- A calibration sweep is taken to begin the sequence.
- The status byte is read until control is requested.
- The computer passes control to the analyzer.
- The display is cleared and the analyzer is set to talker/listener mode.
- The GPIB interface status is read until control is returned.
- The program loops until all the points have been measured.
- The power meter calibration is enabled.
- The calibration data is output to the controller in FORM 4, ASCII format.
- The power meter-calibration factors are read into the controller.
- The analyzer is released from remote control and the program ends.

Running the Program

The analyzer is preset and the power meter-calibration routine begins. The analyzer displays the message “WAITING FOR GPIB CONTROL” when it is requesting control. The system controller display prints “Passing Control” when control is passed to the analyzer. The controller displays “Waiting for request” while the analyzer has control and is reading the power meter.

The interaction of the messages and the movement of the cursor allow observation of the calibration process. Once the calibration is complete, the analyzer displays “POWER METER CAL IS COMPLETE” and the system controller displays “Finished with Power meter Cal”.

The power meter-calibration mode (with one sweep of correction data) is enabled and the calibration is switched on. At the completion of the program, talker/listener mode is restored, the event-status registers are cleared (to halt the status-byte interaction), the power meter correction factors are displayed, the sweep is placed in continuous-sweep mode, the analyzer is released from GPIB control, and the program ends.
BASIC Program Listing

10 ! This routine does a power meter cal using pass control.
20 ! A measurement cycle takes place on each point of the trace. The
30 ! point is measured by the power meter and the measured value read

Analyzer System Setup Examples

Saving and Recalling Instrument States

NOTE

The most efficient option for storing and recalling analyzer states is using the analyzer's internal registers to save the CAL data. Recalling these registers is the fastest solution to restoring analyzer setups. See your analyzer’s user’s guide for detailed information on the analyzer's internal storage registers.

In the event that all the registers have been used, the internal disk drive is not used, or if internal memory limitations exist, then these external solutions become viable.

The purpose of this example is to demonstrate several programming options for storing and recalling entire instrument states over GPIB. The examples describe two different processes for storing and recalling instrument states. The first example accomplishes the task using the learn string. The second example involves reading both the learn string and the calibration arrays out of the analyzer and storing them to disk or storing them in the system controller itself.

Using the learn string is a very rapid way of saving the instrument state, but using direct disk access has the advantage of automatically storing calibrations, cal kits, and data along with the instrument state.

A complete analyzer setup requires sending the learn string and a calibration array to set the analyzer parameters. The CAL array may also be placed in the analyzer, just as if a calibration was performed. By sending both sets of data, the analyzer may be quickly setup for a measurement.

Several different measurements may be required in the course of testing a device. An efficient way of performing multiple measurements is to send both the calibration array and the learn string, and then perform the measurements.

Example 5A: Using the Learn String

The learn string is a very fast and easy way to read an instrument state. The learn string includes all front-panel settings, the limit table for each channel, and the list-frequency table. It can be read out of the analyzer with the command OUTPLEAS, and input to the analyzer with the command INPULEAS.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The string storage is allocated.
- The learn string is requested.
- The string is read without any processing.
• The analyzer is released from remote control.
• The instrument state is changed by the operator.
• The learn string is sent back to the analyzer.
• The analyzer is released from remote control and the program ends.

Running the Program

Run the program. When the program stops, change the instrument state and press Enter on the controller. The analyzer will be returned to its original state by using the learn string.

BASIC Program Listing

```
1! This program shows how to retrieve a learn string from the analyzer
2! into a string array. The state of the analyzer is then changed and the
3! learn string re-loaded to return the analyzer to the previous settings.

34 END
```
Example 5B: Reading Calibration Data

This example demonstrates:

- how to read measurement calibration data out of the network analyzer
- how to read it back into the analyzer
- how to determine which calibration is active

The data used to perform measurement-error correction is stored inside the analyzer in one (or more) of twelve calibration-coefficient arrays. Each array is a specific error coefficient, and is stored and transmitted as an error-corrected data array. Each point is a real/imaginary pair, and the number of points in the array is the same as the number of points in the sweep. The five data formats also apply to the transfer of calibration-coefficient arrays. Your analyzer's user's guide contains information on the storage locations for calibration coefficients and different calibration types.

A computer can read out the error coefficients using the commands OUTPCALC01, OUTPCALC02, ..., through OUTPCALC12. Each calibration type uses only as many arrays as required, beginning with array 1. Hence, it is necessary to know the type of calibration about to be read out. Attempting to read an array not being used in the current calibration causes the "REQUESTED DATA NOT CURRENTLY AVAILABLE" warning.

A computer can also store calibration coefficients in the analyzer. To do this, declare the type of calibration data about to be stored in the analyzer just as if you were about to perform that calibration. Then, instead of calling up different classes, transfer the calibration coefficients using the INPUCALCnn commands. The variables nn are a data pair appended to the command representing a calibration number from 01 through 12. When all the coefficients are stored in the analyzer, activate the calibration by issuing the mnemonic SAVC, and trigger a sweep on the analyzer.

This example reads the calibration coefficients into a very large array, from which they can be examined, modified, stored, or put back into the instrument. If the data is to be directly stored onto disk, it is usually more efficient to use FORM 1 (analyzer's internal-binary format), and to store each coefficient array as it is read in.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- A binary path is assigned.
- The system is initialized.
- The calibration types and number of arrays are defined.
- The integer variables for reading the headers are defined.
- The calibration type and number of arrays are read by the controller.
- The output is formatted in FORM 3.
- The number of points in the trace is read.
- The memory is allocated for the calibration arrays.
- Each calibration array is requested from the analyzer.
- Header information is read with a binary I/O path.
The elements from each calibration array are read in.
The next calibration array is requested until all the arrays have been read.
The calibration type is sent to the analyzer.
Each calibration array is sent.
The calibration is activated.
The analyzer is released from remote control and the program ends.

Running the Program
Before executing the program, perform a calibration.
The program is able to detect which type of calibration is active. With that information, it predicts how many arrays to read out. When all the arrays have been sent to the computer, the program prompts the user. The operator then turns the calibration off or performs a completely different calibration on the analyzer and continues the program. The computer reloads the old calibration. The operator should not preset the analyzer because the instrument settings must be the same as those that were present when the calibration was taken.

NOTE
The retransmitted calibration is associated with the current instrument state: the instrument has no way of knowing the original state associated with the calibration data. For this reason, it is recommended that the learn string be used to store the instrument state whenever calibration data is stored. The next example demonstrates how to reload the analyzer state with both the learn string and the calibration arrays.

Example 5C: Saving and Restoring the Analyzer Instrument State

NOTE
The instrument state may also be stored in the analyzer’s internal registers. This is the fastest and most efficient method for toggling between instrument states. This example is for use when the analyzer’s internal memory is full, or when the are other internal-memory limitations.

This example demonstrates how to use both the learn string and the calibration arrays to completely re-program the analyzer state. If you were performing two entirely different measurements on a device and wanted to quickly change between instrument states and perform the measurements, this example program is a potential solution.

The example will request the learn string and calibration array from the analyzer and store them in a disk file on the system controller. Once the storage is complete, the operator will be prompted to change the state of the analyzer and then re-load the state that was previously stored in the disk file. Once the file is created on the disk, the state information can be retrieved from the controller and restored on the analyzer.

NOTE
The disk file can only be created once. Errors will occur if the operator repeatedly tries to recreate the file.

For this example, only a thru calibration will be performed and transferred. This means only one calibration array will be read from the analyzer and written to the disk file with the instrument state. To work with more elaborate calibrations, additional arrays will need to be defined and transferred to the disk file. This is not difficult, but requires some further programming steps which were omitted in the interest of presenting a simple example.

The following is an outline of the program’s processing sequence:

• An I/O path is assigned for the analyzer.
• A binary path is assigned.
• The integers for reading the headers are defined.
• The system is initialized.
• An array is created to hold the learn string.
• The learn string is requested by the controller.
• The number of points in the trace is read.
• The controller allocates an array for the calibration data.
• The calibration data is read into the controller.
• The controller creates and assigns a data file for the calibration array and the learn string.
• The learn string and calibration array are stored in the disk file.
• The operator presses (Enter) on the controller to read the calibration data back into the analyzer.
• The learn string is read from the disk file and output to the analyzer.
• The calibration array is read in from the disk file and stored in the analyzer.
• The analyzer is returned to continuous-sweep mode.
• The analyzer is released from remote control and the program ends.

Running the Program

Setup the analyzer and perform a through calibration.

Run the program. The program prompts the operator to change the state of the analyzer and then press [Enter] to continue. At this point, the analyzer state is stored on the disk file in the controller. Pressing [Enter] will begin the transfer from the disk file to internal arrays within the controller and then on to the analyzer.

Once completed:
• The original state will be restored.
• The analyzer will be sweeping.
• The analyzer will be calibrated.
• **COR** will be displayed on the analyzer's display.

BASIC Program Listing

```

List-Frequency and Limit-Test Table Examples

Using List Frequency Sweep Mode

The analyzer normally takes data points spaced at regular intervals across the overall frequency range of the measurement. For example, for a 2 GHz frequency span using 201 points, data will be taken at intervals of 10 MHz. The list frequency sweep mode allows the operator to select the specific points, or frequency spacing between points, at which measurements are to be made. This mode of operation allows flexibility in setting up tests that ensure device performance. By only sampling specific points, measurement time is reduced. List frequency sweeps are also discussed in your analyzer’s user’s guide.

The following three example programs illustrate the use of the analyzer’s list frequency sweep mode to perform arbitrary frequency testing. Examples 6A (Stepped List Mode) and 6B (Swept List Mode) allow the operator to construct a table of list frequency segments which is then loaded into the analyzer's list frequency table. There are a maximum of 30 segments available. Each segment stipulates a start and stop frequency, and the number of data points to be taken over that frequency range. In Example 6B (Swept List Mode), each segment also stipulates a power value and IF bandwidth. List frequency segments can be overlapped in the stepped list mode but not in the swept list mode. The total number of points in all the segments must not exceed 1601.

Examples 6A (Stepped List Mode) and 6B (Swept List Mode) take advantage of the computer’s capabilities to simplify creating and editing a list frequency table. The table is entered and completely edited before being transmitted to the analyzer. To simplify the programming task, options such as entering center frequency, frequency span, or step size are not included.

Example 6C lets the operator select a specific segment to “zoom-in.” A single instrument can be programmed to measure several different devices, each with its own frequency range, using a single calibration. When a specific device is connected, the operator selects the appropriate segment for that device.

The command sequence for entering a list frequency table imitates the key sequence followed when entering a table from the front panel: there is a command for every key-press. Editing a segment is also the same as the front-panel key sequence, but the analyzer automatically reorders each edited segment in order of increasing start frequency.

The list frequency information may be acquired using the limit-test results array. The actual stimulus points are available as the first element in the array. The list frequency table is also carried as part of the learn string. While the table cannot be modified as part of the learn string, it can be stored and recalled with very little effort by storing and recalling the learn string. See “Example 5A: Using the Learn String” on page 7-79 and “Learn String and Calibration-Kit String” on page 5-7 for details on using learn strings.
Example 6A: Setting Up a List Frequency Table in Stepped List Mode

The purpose of this example is to show how to create a list frequency table in stepped list mode and then transmit the table to the analyzer.

In the stepped list mode, the source steps to the next frequency point where it stops long enough for the analyzer to take data. For electrically long devices, this mode ensures that the measurement will not be impacted by IF delay. In addition, this mode provides the most flexibility in specifying the list of frequencies.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The existing list frequencies are edited and cleared.
- The number of segments to define is read in.
- An array for the list segments is defined.
- The parameters for each segment are requested.
- If the operator wants to edit, the segment parameters are re-entered.
- The new list is sent to the analyzer.
- The analyzer is released from remote control and the program ends.

Running the Program

The program displays the frequency list table as it is entered. During editing, the displayed table is updated as each line is edited. The table is not re-ordered. At the completion of editing, the table is entered into the analyzer, and list frequency sweep mode is switched ON. During editing, pressing Enter leaves an entry at the old value.

The start frequency, stop frequency, and number of points for the last segment entered may be observed on the analyzer's display.

Activate a marker and select the discrete-marker mode to observe the point spacing. Use an exaggerated scale with just a few points to find the list-frequency spacing between points.

BASIC Program Listing

```

Example 6B: Setting Up a List Frequency Table in Swept List Mode

The purpose of this example is to show how to create two tables: a list frequency table in swept list mode, and a limit-test table. Both tables are then transmitted to the analyzer.

In the swept list mode, the source sweeps through each segment, with the analyzer taking data during the sweep. This can increase throughput by up to 6 times over a stepped sweep. In addition, this mode expands the list table to include a power value and IF bandwidth for each defined segment. The only restriction is that you cannot specify segments with overlapping frequencies. For more information on the swept list mode, refer to your analyzer’s user’s guide.

The following is an outline of the program's processing sequence:

- An array for the type of limit line is defined and initialized.
- An array for the list table (frequency list and limit lines) is defined and initialized with data.
- An I/O path is assigned for the analyzer.
- The system is initialized.
- A variable is initialized with the number of segments in the list table.
- The analyzer is placed into hold mode and (for ES model analyzers) the port powers are uncoupled for the active channel.
- The existing list frequencies are edited and the analyzer swept list mode is selected.
- The analyzer is instructed to set the IF bandwidth and port power levels according to the values from the list table.
- The new frequency list table is sent to the analyzer.
- The sweep mode is set to list frequency mode and S21 (transmission) measurement. A single sweep is taken.
- The analyzer display is autoscaled.
- The existing limit lines are edited and cleared.
- The new limit table is sent to the analyzer.
- The limit lines and limit test are turned on.
- The analyzer is released from remote control and the program ends.

The program is written as follows:

Running the Program

The program requires no input from the operator. The list frequency table data and limit-test table data is read directly from the program code into the array. Next, the analyzer is set up to respond to the IF bandwidth and port power parameters of the list frequency table. After the list frequency data is entered into the analyzer, the list frequency sweep mode is initiated and a single sweep is taken. Lastly, the limit-test table data is entered into the analyzer and the limit lines and limit test are activated.

The analyzer should now indicate whether the measurement trace passes or fails the limit test.

Example 6C: Selecting a Single Segment from a Table of Segments

This example program demonstrates how to define a single segment as the operating-frequency range of the analyzer from a table of segments stored in the controller. The program assumes that a list frequency table has already been entered into the analyzer, either manually, or using the program in Example 6A or Example 6B.

The program first loads the list frequency table into the computer by reading the start and stop frequencies of each segment and the number of points for each segment. The segment’s parameters are then displayed on the computer screen, and the operator can choose which segment is to be used by the analyzer. Note that only one segment can be chosen at a time.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The list frequency segment is edited.
- The largest segment number is set.
- The highest segment number is requested.
- The number of actual segments is read in.
- A list frequency table is defined and the segments are read in to the controller from the analyzer.
- The operator selects one of the segments of the sweep.
- The controller “zooms-in” and sweeps the defined segment.
- The operator ends the program by entering segment number “0.”
- The analyzer returns to sweeping all the segments in the table.
- The activation loop is ended and the program ends.

Running the Program

The program will read the parameters for each list-frequency segment from the analyzer, and build a table containing all the segments. The parameters of each segment will be printed on the computer screen. If there are more than 17 segments, the program will pause. Press (Return) to see more segments. The maximum number of segments that can be read is 30 (the maximum number of segments the analyzer can hold). Use the computer's (Page Up) and (Page Down) keys to scroll through the list of segments if there are more than 17.

After all the segments are displayed, the program will prompt the operator for a specific segment to be used. Type in the number of the segment, and the analyzer will then “zoom-in” on that segment. The program will continue looping, allowing continuous selection of different segments. To exit the loop, type 0. This will restore all the segments (with the command ASEG), allowing the analyzer to sweep all of the segments, and the program will terminate.
BASIC Program Listing

10 ! This program shows how to select a single segment from a list
20 ! frequency sweep and activate it as the sweep. The list frequency
30 ! table is read from the analyzer and displayed on the computer
40 ! screen. The operator is prompted to select a segment and the
50 ! program then activates it. All the segments are activated upon
60 ! completion.

Using Limit Lines to Perform PASS/FAIL Tests

There are two steps to performing limit testing on the analyzer via GPIB. First, limit specifications must be defined and loaded into the analyzer. Second, the limits are activated, the device is measured, and its performance to the specified limits is signaled by a pass or fail message on the analyzer’s display.

Example 6D illustrates the first step, setting up limits. Example 6E performs the actual limit testing.

Example 6D: Setting Up a Limit-Test Table

The purpose of this example is to show how to create a limit-test table and transmit it to the analyzer.

The command sequence for entering a limit-test table imitates the key sequence followed when entering a table from the analyzer’s front panel: there is a command for every key-press. Editing a limit line is also the same as the key sequence, but remember that the analyzer automatically re-orders the table in order of increasing start frequency.

The limit-test table is also carried as part of the learn string. While it cannot be modified as part of the learn string, the learn string can be stored and recalled with very little effort. See “Example 5A: Using the Learn String” on page 7-79 and “Learn String and Calibration-Kit String” on page 5-7 for details on using learn strings.

This example takes advantage of the computer’s capabilities to simplify creating and editing the table. The table is entered and completely edited before being transmitted to the analyzer. To simplify the programming task, options such as entering offsets are not included.

This example automates the front-panel operation of entering a limit-test table. Front-panel operation and limits are discussed in your analyzer’s user’s guide.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The limit lines are edited and cleared.
• The number of limits is requested.
• The limit table is created.
• The string array of limit types is created.
• The operator is prompted to enter the new limit values.
• The new limit table is sent back to the analyzer.
• The limit line is activated.
• The limit test is activated.
• The analyzer is returned to local control and the program ends.

Running the Program

CAUTION    This example program will delete any existing limit lines before entering the new limits. If this is not desired, omit the line(s) that clear the existing limits (in this case, the command “CLEL;” contained in LINE 190). This program begins by presetting the analyzer. The programmer will have to add the necessary command lines to set the analyzer to the operating conditions required for testing. The example program will show the limit lines defined, but the limits will always fail without additional analyzer setup.

The program displays the limit table as it is entered. During editing, the displayed table is updated as each line is edited. The table is not reordered. At the completion of editing, the table is entered into the analyzer, and limit-testing mode switched ON. The analyzer will rearrange the table in ascending order starting with the lowest start frequency entry. During editing, simply pressing Enter leaves an entry at the old value.

BASIC Program Listing

10  ! This program shows how to create a limit table and send it to the analyzer. The operator enters the desired limits when prompted for the stimulus value, upper and lower value and type of limit desired. Once the table is created, the limits are sent to the analyzer and activated.

Example 6E: Performing PASS/FAIL Tests While Tuning

The purpose of this example is to demonstrate the use of the limit/search-fail bits in event-status register B, to determine whether a device passes the specified limits. Limits can be entered manually, or using Example 6D.

The limit/search-fail bits are set and latched when limit testing or a marker search fails. There are four bits, one for each channel for both limit testing and marker search. See Figure 6-1 on page 6-3 and Table 4-1 on page 4-5 for additional information. Their purpose is to allow the computer to determine whether the test/search executed was successful. They are used in the following sequence:

1. Clear event-status register B.
2. Trigger the limit test or marker search.
3. Check the appropriate fail bit.

When using limit testing, the best way to trigger the limit test is to trigger a single sweep. By the time the single sweep command (SING) finishes, limit testing will have occurred.

**NOTE**

If the device is tuned during the sweep, it may be tuned into and then out of limit, causing a limit test to qualify as “passed” when the device is not in fact within the specified limits.

When using marker searches (max, min, target, and widths), outputting marker or bandwidth values automatically triggers any related searches. Therefore, all that is required is to check the fail bit after reading the data.

In this example, several consecutive sweeps must qualify as “passing” in order to ensure that the limit-test pass was not extraneous due to the device settling or operator tuning during the sweep. Upon running the program, the number of “passed” sweeps for qualification is entered. For very slow sweeps, a small number of sweeps such as two are appropriate. For relatively fast sweeps, where the device requires time to settle after tuning, as many as six or more sweeps may be more appropriate.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The pass counter is initialized on entry.
- The analyzer takes a sweep.
- The event-status register B byte is output and the channel-1 limit is tested.
- If the device fails the first sweep, the operator is prompted to ensure it is tuned correctly and the device is measured again.
- If the device passes the first sweep, the operator is prompted not to touch the device as testing continues.
- If the device passes the required number of sweeps, the operator is prompted that the device has passed and to connect the next device for testing.
- The program initializes the pass counter and begins to measure the new device.
Running the Program

NOTE  This program assumes a response calibration (through calibration) or a full 2-port calibration has been performed prior to running the program.

Set up a limit-test table on channel 1 for a specific device either manually, or using the program in Example 6D.

Run the program, and enter the number of passed sweeps desired for qualification. After entering the qualification number, connect the device. When a sweep passes, the computer beeps. When enough consecutive sweeps qualify the device as “passing,” the computer emits a dual-tone beep to attract the attention of the operator, and then prompts for a new device.

To test the program's pass/fail accuracy, try causing the DUT to fail by loosening the cables connecting the DUT to the analyzer and running the program again.

BASIC Program Listing

10  ! This program demonstrates Pass/Fail tests using limit lines. The  
20  ! program uses the latch-on-fail limit bits in event status register  
30  ! B to determine if the device performance passes the specified test  
40  ! limit lines. It then requires that the device passes for multiple  
50  ! consecutive sweeps in order to ensure that the device is static in  
60  ! the response and not varying. The operator specifies how many sweeps  
70  ! are required to pass the test.

Report Generation Examples

The analyzer has three operating modes with respect to GPIB. These modes can be changed by accessing softkeys in the (Local) menu. System-controller mode is used when no computer is present. This mode allows the analyzer to control the system. The other two modes allow a remote system controller to coordinate certain actions: in talker/listener mode the remote system controller can control the analyzer, as well as coordinate plotting and printing; and in pass-control mode the remote system controller can pass active control to the analyzer so that the analyzer can plot, print, control a power meter, or load/store to disk. The amount of peripheral interaction is the main difference between talker/listener and pass-control mode.

Example 7A: Operation Using Talker/Listener Mode

The commands OUTPLOT and OUTPRIN allow talker/listener mode plotting and printing via a one way data path from the analyzer to the plotter or printer. The computer sets up the path by addressing the analyzer to talk, the plotter to listen, and then releasing control of the analyzer in order to transfer the data. The analyzer will then make the plot or print. When it is finished, it asserts the End or Identify (EOI) control line on GPIB. The controller detects the presence of EOI and re-asserts control of the GPIB. This example program makes a plot using the talker/listener mode.

NOTE One of the attributes of the OUTPLOT command is that the plot can include the current softkey menu. The plotting of the softkeys is enabled with the PSOFTON; command and disabled with the PSOFTOFF; command.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The selected frequency span is swept once.
- The plot command is sent to the analyzer.
- The analyzer is set to talker mode and the plotter is set to listener mode.
- The plot is spooled to the plotter.
- The analyzer is set to listener mode when the controller detects an EOI from the analyzer.
- The controller puts the analyzer back in continuous-sweep mode.
- The analyzer is returned to local control and the program ends.

Running the Program

The analyzer will go into remote, and make the plot. During the plot, the computer will display the message Plotting and waiting for EOI. When the plot is completed, the analyzer asserts the EOI line on the GPIB. The computer detects this and displays the End of plot message.
If a problem arises with the plotter, such as no pen or paper, the analyzer cannot detect the situation because it only has a one-way path of communication. Hence, the analyzer will attempt to continue plotting until the operator intervenes and aborts the plot by pressing the analyzer’s Local key.

Pressing Local will do the following:

- Aborts the plot.
- Causes the warning message CAUTION: PLOT ABORTED.
- Asserts EOI to return control of the bus to the system controller.

Because of possible peripheral malfunctions, it is generally advisable to use pass-control mode, which allows two way communication between the peripherals and the analyzer.

**BASIC Program Listing**

```
10 ! This example shows a plot operation under the control of the
20 ! analyzer. The analyzer is commanded to output plot data, the
30 ! plotter is addressed to listen, and the analyzer to talk. The
40 ! controller watches for EOI at the end of the plot sequence and
50 ! then regains control of the HP-IB operations.

Example 7B: Controlling Peripherals Using Pass-Control Mode

NOTE  This example program will not work with HP BASIC for Windows.

If the analyzer is in pass-control mode and it receives a command telling it to plot, print, control a power meter, or store/load to disk, it sets bit 1 in the event-status register to indicate that it requires control of the bus. If the computer then uses the GPIB pass-control command to pass control to the analyzer, the analyzer will take control of the bus and access the peripheral. When the analyzer no longer requires control, it will pass control back to the computer.

In this example, the pass-control mode is used to allow the network analyzer to dump a screen display to a printer.

Pass-control mode allows the analyzer to control the printer while sending the screen display to be printed. The analyzer requests control from the instrument controller and the controller allows the analyzer to take control of the GPIB and dump the plot. The instrument controller must not interact with the GPIB while this remote analyzer control is taking place. Once the printer-dump operation is complete, the analyzer passes control back to the controller and the controller continues programming the analyzer.

NOTE  The analyzer assumes that the address of the computer is correctly stored in its GPIB addresses menu under [Local] SET ADDRESSES ADDRESS: CONTROLLER. If this address is incorrect, control will not return to the computer. Similarly, if control is passed to the analyzer while it is in talker/listener mode, control will not return to the computer.

Control should not be passed to the analyzer before it has set event-status-register bit 1 making it Request Active Control. If the analyzer receives control before the bit is set, control is passed immediately back to the controller.

When the analyzer becomes the active system controller, it is free to address devices to talk and listen as required. The only functions denied the analyzer are the ability to assert the interface clear line (IFC), and the remote line (REN). These are reserved for the master system controller. As the active system controller, the analyzer can send and receive messages from printers, plotters, and disk drives.

The following is an outline of the program's processing sequence:

• An I/O path is assigned for the analyzer.
• The system is initialized.
• The status registers are cleared.
• Bit 1 of ESR request control is set.
• The ESR interrupt for SRQ is enabled.
• The pass-control mode is enabled.
• The data is dumped to the printer.
• The program loops until the SRQ bit is set.
• The status byte is read with a serial poll.
• The program tests for bit 6, SRQ.
• If SRQ is detected, the program tests for pass control (bit 5 of the status byte).
• If the analyzer requests control, the system controller gives the analyzer control of the bus.
• The program loops and waits for the analyzer to complete the print dump.
• The analyzer reads the interface.
• If bit 6 is active in the controller, control is returned from the analyzer to the controller.
• The status-byte assignments are cleared.
• The analyzer returns to continuous-sweep mode.
• The analyzer is returned to local control and the program ends.

Running the Program
The analyzer will briefly flash the message **WAITING FOR CONTROL**, before actually receiving control and generating the printer output. The computer will display the **Printing from analyzer and waiting for control** message.

When the printer output is complete, the analyzer passes control back to the address stored as the controller address under the **Local** **SET ADDRESSES** menu. The computer will detect the return of active control and exit the wait loop. The controller will display the **Control returned from analyzer** message and then release the analyzer from remote control.

**NOTE** Because the program waits for the analyzer's request for control, it can be used to respond to front-panel requests as well. Remove the **PRINALL;** command from the program and run the program. Nothing will happen until the operator requests a print, plot, or disk access from the front panel of the analyzer. For example, press **Local Copy** and **PRINT MONOCHROME**.

**BASIC Program Listing**

```
10  ! This example shows a pass-control operation to print the display
20  ! under the analyzer HP-IB control. The controller reads the status
30  ! of the analyzer looking for SRQ to indicate that the analyzer is
40  ! requesting control. Once control is passed to the analyzer, the
50  ! controller monitors the status of its interface registers to detect
60  ! when the interface is again the active controller. The analyzer will
70  ! pass control back to the controller when finished.

Example 7C: Printing with the Parallel Port

This program will select the parallel port and program the analyzer to copy its display to a printer. There are a number of commands associated with the serial and parallel ports which allow you to configure output modes such as the baud rate and the handshake type used by the port and the printer. In this example, the parallel port is configured by the program. The interface may also be configured from the analyzer’s front-panel keys by pressing [Local SET ADDRESSES PRINTER PORT]. This menu allows manual selection of the parallel-interface parameters.

Since the GPIB port is not being used for the copy operation, programming of the analyzer and measurement operations may continue once the copy operation has been initiated. An internal spooler in the analyzer’s memory provides buffering of the printer operation. In the example which follows, the status byte of the analyzer is checked to determine when the print operation is complete.

• An I/O path is assigned to the analyzer.
• The analyzer is initialized.
• A single sweep is taken and the analyzer is placed in hold mode.
• The status registers are cleared.
• The copy-complete bit is set and enabled.
• The printer operation and communication modes are set.
• The print command is sent.
• The analyzer is released from remote control and placed in continuous-sweep mode.
• The analyzer is polled until the status bit representing copy complete is detected.
• The analyzer is released from remote control and the program ends.

Running the Program

Run the program. The analyzer is initialized, set to single-sweep mode, and a sweep is taken. The program sets the system up to print the analyzer’s display to a printer connected to the parallel port. At this time, the analyzer can continue making measurements as printer prints the display. When the analyzer display has finished printing, the controller displays the message: “DONE”, the analyzer is released from GPIB control, and the program ends.

Example 7D: Plotting to a File and Transferring the File Data to a Plotter

Another report-generation technique is to transfer the plotter string to a disk file, and retrieve and plot the disk file at another time. Test time is increased when a hardcopy plot occurs during the measurement process. It may be more convenient to plot the data at another site or time. One solution to this problem is to capture the plot data using the controller and store it to a disk file. This disk file may then be read from the controller and the contents transferred to a plotter. This next example shows a method of accomplishing this task.

The analyzer is initialized without presetting the analyzer. The data that is in place on the analyzer is not disturbed by the program operation. A large string is dimensioned to hold the plotter commands as they are received from the analyzer. The length of this string depends upon the complexity of the analyzer's display. The analyzer is placed in the single-sweep mode and `OPC?; SING;` is used to make sure that operation is complete before plotting. The plotting begins with the `OUTPLOT;` command.

The string transfer is ended by the controller detecting the EOI line which the analyzer pulls at the end of the transfer. The string transfer terminates and the plot data is now stored in a string in the analyzer.

These strings contain ASCII characters which represent the plotter commands in HP-GL (Hewlett-Packard Graphics Language). A disk file is created and the string is written into the file containing the display-plot commands.

Once the strings are transferred to the disk file, the file pointer is rewound and the data is read out into a string for plotting. The string is sent to the plotter which uses the commands to generate a plot.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- An I/O path is assigned for the plotter.
- The system is initialized.
- The string for plotter commands is defined.
- The frequency span is swept once.
- The plotter output is requested and read into the plot string.
- A plot file is created in the controller.
- The plot string is stored into the disk file.
- The plot string is read from the disk file and sent to the plotter.
- The analyzer returns to continuous-sweep mode.
- The analyzer is returned to local control and the program ends.

Running the Program

The program begins by initializing the analyzer and placing it into single-sweep mode. The plotter commands are captured into strings in the controller. The controller display
Programming Examples
Report Generation Examples

Prompts Plotter output complete. Press RETURN to store on disk. Pressing Return causes the data to be stored to disk. Once this task is complete, the program prompts once more, Plot to file is complete. Press Return to plot. After pressing Return again, the string output is sent to the plotter and the plot begins. Once the plot is complete, the program prompts Plot is complete. End of program. and the analyzer begins sweeping and returns to local control.

BASIC Program Listing

10 ! This program shows how to read the plotter output from the analyzer and store it in a disk file as an ASCII file. The disk file is then
30 ! read back into the controller and the plot commands sent to a
40 ! plotter to generate the plot of the analyzer display. This allows
50 ! plotting at a different time than data collection.

Utilizing PC-Graphics Applications Using the Plot File

You can use Example 7D to generate a plot that can be read into a PC and used in several different graphics generation programs. HP-GL is a commonly recognized graphic format and may be used to transfer information to PC application programs such as CorelDRAW!®, Lotus Freelance® and other graphics packages. By importing the graphics data into these application packages, you can generate reports in many word-processors.

You can then use graphic-data files to generate the following:

- test results documentation
- data sheets from testing results
- archival information for a digital-storage medium

If you would like to create a disk file for graphics processing, modify the previous program to only store the plotter commands to the disk file. Once the file is renamed to include the extension “.hpg”, the PC will have a DOS-format file that can be imported and examined by the graphics package.

Once the HP-GL file is present in the DOS file system, the HP-GL file is imported and examined with the graphics package. The text labels may need to be rescaled, but on the whole, the graphics results are quite usable.

Example 7E: Reading Plot Files from a Disk

NOTE
This example program will not work with HP BASIC for Windows.

This example program reads and plots files which have been stored on a LIF formatted disk by the analyzer. The plots may be sent to either a plotter with auto-feed capability, such as the HP 7550B, or an HP-GL/2 compatible printer, such as a LaserJet 4 Series (monochrome) printer or a DeskJet 1200C (color) printer.

NOTE
Sending plots to disk is discussed in your analyzer’s user’s guide.

This section provides detailed information on file naming conventions and instructions on printing multiple plots-per-page.

This program requires HP BASIC 6.0 or greater which provides the use of wild cards with the catalog command.

The peripheral GPIB addresses and the hard copy device selection are hard coded and may need to be changed for different systems configurations. Refer to lines 1130 through 1240 in the example program.

This program example provides the form feeds to separate the plots. If the analyzer has been configured to store multiple plots-per-page, this program will generate those plots. A file naming convention has been devised to allow the program perform several printer-setup functions. These include: initializing the printer for HP-GL/2 at the beginning of a page, configuring the printer to plot multiple plots to the same page, if desired, and then sending a page eject (form feed) to the hardcopy device at the completion of the printing process.
Programming Examples

Report Generation Examples

The plot file name is made up of four parts. The first three are generated automatically by the analyzer whenever a plot is requested:

1. the prefix “PLOT”
2. a two-digit sequence number in the range of 00 to 31
3. a two-letter output-format code to indicate the plot quadrant position:
   • LU (Left Upper)
   • LL (Left Lower)
   • RU (Right Upper)
   • RL (Right Lower)
   • FP (Full Page)

For example, the first full page plot to a disk would be named “PLOT00FP.” The second plot, to be located in the lower-right hand corner of the page would be named “PLOT01RL,” and so on.

The fourth part is an optional character. It is used to indicate that the file is part of a multiple-file plot on the same graticule. See your analyzer’s user’s guide for information on printing multiple measurements per page.

For detailed information on plotting to disk and outputting the plot files to a printer/plotter see your analyzer’s user’s guide.

The following is an outline of the program’s processing sequence:

• Hardcopy device control strings are created.
• The hardcopy output device is defined.
• The disc storing the file names is cataloged.
• Files that match the name specifier in the file name array (Flnm$) are counted.
• Flnm$ is dimensioned for the number of files that match the name specifier.
• The file name array is sorted.
• A form feed is sent to the hardcopy device.
• Each of the files in the file name array is processed and sent to the output device.
  ❏ The current file name root string is defined.
  ❏ If the hardcopy device is a printer, then an HP-GL initialization string is output.
  ❏ Each file which matches the file name root string to the hardcopy device is output.
  ❏ After a form feed is sent to the hardcopy device, the printing/plotting process begins.

Running the Program

This program allows you to plot or print as many as four analyzer display dumps (stored on a LIF formatted disk) on one side of a single sheet of paper. Refer to the instructions detailed in your analyzer’s user’s guide.
BASIC Program Listing

Example 7F: Reading ASCII Disk Files to the Instrument Controller’s Disk File

Another way to access the analyzer’s test results is to store the data onto a disk file from the analyzer. This operation generates an ASCII file of the analyzer data in a CITIFILE format. A typical file generated by Example 7F is shown below:

```
CITIFILE A.01.00
#NA VERSION HP8753C.04.13
NAME DATA
VAR FREQ MAG 11
DATA S[1,1] RI
SEG_LIST_BEGIN
SEG 100000000 200000000 11
SEG_LIST_END
BEGIN
  8.30566E-1,-1.36749E-1
  8.27392E-1,-1.43676E-1
  8.26080E-1,-1.52069E-1
  8.26385E-1,-1.68029E-1
  8.26507E-1,-1.77154E-1
  8.26263E-1,-1.87316E-1
  8.26721E-1,-1.97265E-1
  8.2724E-1,-2.07611E-1
  8.28552E-1,-2.19940E-1
  8.29620E-1,-2.31109E-1
END
```

This data file is stored by the analyzer under remote control or manually from the front panel. See your analyzer’s user’s guide for more details on manual operation. This program performs the same steps that are required to manually store a file from front panel.

This program stores a file in the same manner as an operator would store a file onto the analyzer’s internal disk drive from the front panel.

This example explains the process of storing the data from the analyzer to a file on the internal disk drive. There is also a program to read the data from the file into a data array for further processing or reformatting to another file type. The internal drive will store in the same format that is present on the disk. A new disk may be formatted in either LIF or DOS. For the example, the assumption has been made that the format transformation has already taken place, and there is a file that can be read record by record, from which data can be retrieved.

The goal of this example is to recover an array of stimulus frequency along with the trace-data values. CITIFILES contain the real and imaginary values of each data point. Some further transformation will be required to obtain magnitude values, for example.

The disk file contents for this example are shown above. This file contains more information than will be used in this example. The file is accessed and the records read from the file and printed on the controller display to observe the actual file contents. The file pointer is reset and the records are then read and interpreted for their data contents.

The first six records are skipped for this example. The seventh record contains the stimulus-frequency values and the number of points in the trace. These values are read from the record. The frequency increment, or point spacing, is calculated and used later in
the frequency-data calculations for a point. Two more records are skipped and the next is the first record representing data values. The data values are read in a loop until the values for the number of points have been recovered from the file. The data values are tabulated and printed out on the controller display.

The following is an outline of the program's processing sequence:

• An I/O path is assigned to the analyzer.
• The system is initialized.
• A string is dimensioned to hold a file record.
• The analyzer operating state is set.
• The internal drive is selected for storage (only ASCII data is stored).
• A file name is entered and the data stored into it.
• The operator is prompted to move the disk to the controller disk drive.
• The disk file is read and the contents displayed.
• The file pointer is rewound.
• The file contents are converted to trace data.
• The frequency and complex-data pair is displayed for each point.
• The analyzer is restored to continuous-sweep mode.
• The analyzer is returned to local control and the program ends.

CAUTION  Do not mistake the line switch for the disk eject button. If the line switch is mistakenly pushed, the instrument will be turned off, losing all settings and data that have not been saved.

NOTE  If the command EXTMDATON is used, it will override all of the other save options (such as EXTMFORMON). Because this type of data is only intended for computer manipulation, the file contents of a EXTMDATON (data only) save cannot be recalled and displayed on the analyzer.

Running the Program

The analyzer is initialized and the operating range re-defined to an 11-point trace from 100 to 200 MHz. This setup gives a restricted range to be evaluated when the ASCII data file (CITIFILE) is read in from the controller. The operator is prompted for a 5-character filename to use for storing the data. The analyzer is setup for external storage and stores the data file. Once the “pass control/storage/return control” operation is complete, the operator is prompted to place the disk in the controller disk drive and press (Return). The disk is then read and the records contained in the file are printed on the controller display. A prompt appears, Press return to continue, which allows viewing of the file contents. Once (Return) is pressed, the data records are read and decoded and a table of the stimulus frequency and the data values are printed.

Mixer Measurement Example

The program included in Example 8A is one of several mixer measurements discussed in your analyzer’s user’s guide.

NOTE This example program is for use on any 8753ET/ES analyzer and on 8720E series analyzers with Option 089.

Example 8A: Comparison of Two Mixers — Group Delay, Amplitude or Phase

Using this program, you can measure how two mixers compare in terms of group delay, amplitude or phase. Refer to Figure 7-2.

Figure 7-2 Connections: Comparison of Two Mixers — Group Delay, Amplitude or Phase
The following is an outline of the program's processing sequence:

- I/O paths are assigned for the analyzer and external source.
- The system is initialized.
- The system operator is prompted for the LO and IF frequencies.
- The external source frequency and power level are adjusted.
- The analyzer's IF frequency settings and power level are adjusted.
- The frequency offset mode settings are initialized and the mode is activated.
- A response calibration is performed.
- The system operator is prompted for the type of measurement.
- The selected type of measurement is performed and the display is autoscaled.
- The analyzer and source are released from remote control and the program ends.

**NOTE**

When running the program, the following message may appear:

"CAUTION: PHASE LOCK CAL FAILED". This message is expected and will disappear once the prompted frequency values are entered.

---

**Running the Program**

The analyzer and source are initialized and the operator is queried for the LO frequency, IF center frequency and span. The source frequency and power level are set, and the analyzer frequency settings and power level are adjusted as well. The analyzer frequency offset mode settings are adjusted, the frequency offset mode is turned on, and a response calibration is performed. The operator is queried for the type of measurement, which is then performed, and the program ends.

Limit Line and Data Point Special Functions

The analyzer has special functions in the area of limit testing and in the detection of min/max data points within limit segments. The information in this section will teach you how to use these limit line and data point special functions. The following topics are included:

- Overview
- Constants Used Throughout This Document
- Output Limit Test Pass/Fail Status Per Limit Segment
- Output Pass/Fail Status for All Segments
- Output Minimum and Maximum Point Per Limit Segment
- Output Minimum and Maximum Point For All Segments
- Output Data Per Point
- Output Data Per Range of Points
- Output Limit Pass/Fail by Channel

Overview

The limit line and data point special functions are available as remote commands only. Each command is overviewed in Table 7-11.

† For the definition of a limit segment, see “Example Display of Limit Lines” on page 7-128.
Limit Line and Data Point Special Functions

Example Display of Limit Lines

The features that output data by limit segment are implemented based on the current definition of a limit segment. The actual limit lines formed by the limit table almost never have a 1-for-1 relationship with the segment numbers in the limit edit table. Out of 18 segments in the limit table, you can create 18 limit lines if (a) all limit segments are contiguous and (b) the last segment extends to the stop frequency. Otherwise, terminating a segment requires a single point which means that constructing a limit line requires two entries (segments) of the limit table. Thus you have a minimum of 9 lines available and those lines will not be referenced by sequential segment numbers.

Figure 7-3 is an example of a screen print of limit lines set up on the two instrument channels. The limit line examples shown are of Flat Line, Slope Line and Single Point Limits. See Table 7-12.

* No test limit-segment is created.

Note that if a single point limit is used to terminate slope lines, no test limit-segment is created. (See Figure 7-3: CH1, Seg4.) Also, if a single point limit is used to terminate a flat line, no test limit-segment is created. (See Figure 7-3: CH1, Seg2.) However, if the single point limit used to terminate the flat line limit has different limit values, a single-point test limit-segment is created. (See Figure 7-3: CH2, Seg2.)

Output Results

Table 7-13 shows the output of the OUTPSEGAM test (min/max of all active segments); note that the segments with asterisks (*) from Table 7-12 have no output in Table 7-13.

Constants Used Throughout This Document

NOTE The logic values attached to pass and fail indicators were chosen to be consistent with the current logic used in the standard OUTPLIML and OUTPLIMF commands.

Table 7-14 Pass/Fail/No_Limit Status Constants

<table>
<thead>
<tr>
<th>Status Definition</th>
<th>Status Indicator</th>
</tr>
</thead>
<tbody>
<tr>
<td>PASS</td>
<td>1</td>
</tr>
<tr>
<td>FAIL</td>
<td>0</td>
</tr>
<tr>
<td>NO_LIMIT</td>
<td>-1</td>
</tr>
</tbody>
</table>

Table 7-14 is an interpretation of the Pass/Fail/No_Limit status constants. These constants are used to identify the Pass/Fail/No_Limit state on the data strings if status is returned.

Table 7-15 Min/Max Test Constants

<table>
<thead>
<tr>
<th>String</th>
<th>Stimulus Value</th>
<th>Data Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_DATA</td>
<td>0</td>
<td>-1000</td>
</tr>
</tbody>
</table>

Table 7-15 is an interpretation of the min/max test constants. If the selected segment has no associated limit, the NO_DATA string is generated, which reports a stimulus value of 0 and a data value of −1000.

Output Limit Test Pass/Fail Status Per Limit Segment

Two commands allow you to query the pass/fail test status on a limit segment basis.

- `SELSEG<num>` will select the segment.
- `OUTPSEGF` will return the status of the limit test for that segment: 1 (PASS), 0 (FAIL) or −1 (NO_LIMIT) if no limit exists for the selected segment number. Due to the non-sequential numbering of actual limit line segments on the screen, some segment numbers will have no associated limits and will thus return −1 (NO_LIMIT).

Under the following conditions, `OUTPSEGF` will issue the following errors:

- If the limit testing is off: “30: Requested Data Not Currently Available.” To clear the error message, turn the limit test on.
- If the limit table is empty: “204: Limit Table Empty” (this is a new message). To clear the error message, enter a limit table.

In both cases, the error is issued and the command responds with −1 (NO_LIMIT).

The argument for `SELSEG<num>` is limited by the maximum number of segments allowed in the limit table, which is currently 18. The minimum value for the argument is 1. If the user inputs a number that is outside this range, the active entry limits are invoked, causing the analyzer to return the status for limit 18.
Example:
Sending SELSEG3 and OUTPSEGF may return the following:

1 (segment number 3 passed)

NOTE The output is ASCII. Currently, the formatting for integer numbers appears to append a trailing space.

Output Pass/Fail Status for All Segments

The GPIB command OUTPSEGAF will return the number of segments being reported, followed by pairs of data consisting of the segment number and its status. A segment is reported only if it has an associated limit. The output is only valid if limit test is on. See “Output Limit Test Pass/Fail Status Per Limit Segment” on page 7-131.

Example:
Sending OUTPSEGAF may return the following:

3
1, 0
3, 1
5, 0

For an explanation of these results, see Table 7-16.

NOTE A new Line Feed character <LF> is inserted after the number of segments and after each data pair.

Table 7-16 Example Output: OUTPSEGAF (pass/fail for all segments)

<table>
<thead>
<tr>
<th>Segments Reported</th>
<th>Segment Number</th>
<th>Status</th>
<th>Status Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>FAIL</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>PASS</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>FAIL</td>
<td></td>
</tr>
</tbody>
</table>

Table 7-16 is an interpretation of the data returned by the command OUTPSEGAF. For clarification, status definition is also included.
Example Program of OUTPSEGAF Using BASIC

The following program is not included on the “Programming Examples” CD-ROM:

```
10 OUTPUT 716; "outpsegaf;"
20 ENTER 716; Numsegs
30 PRINT "Receiving status for"; Numsegs; "segments."
40 IF Numsegs>0 THEN
50    FOR I=1 TO Numsegs
60        ENTER 716; Segnum, Pf
70    PRINT USING "DD, 2X, 8A"; Segnum, Pf
80 NEXT I
```

The example program shows how the OUTPSEGAF command can be used to request the number of active segments and their status. Notice that each segment result must use a new enter command as a line feed terminates each segment data result.

Output Minimum and Maximum Point Per Limit Segment

The command MINMAX<ON|OFF> toggles a feature which records the minimum and maximum data points in all active limit segments. Note that limit testing need not be turned on.

The command OUTPSEGM will report the min/max data for the segment previously selected by SELSEG. The data is returned in a comma delimited string with the segment number, minimum point stimulus, minimum trace value, maximum point stimulus and maximum trace value.

Under the following conditions, OUTPSEGM will issue the following errors:

- If the min/max testing is off: “30: Requested Data Not Currently Available.” To clear the error message, turn the min/max testing on.
- If the limit table is empty: “204: Limit Table Empty” (this is a new message). To clear the error message, enter a new limit table.

When the above error conditions occur, there is no data to report, thus no output is generated.

If the selected segment has no associated limit, the NO_DATA string is generated, which reports a stimulus value of 0 and a data value of $-1000$. 

**Example:**

Sending `SELSEG3` and `OUTPSEGM` may return the following:

3, 1.900000000E+09, −9.900000E−01, 2.123456789E+09, 2.123456E+00

For an explanation of these results, see Table 7-17.

**Table 7-17 Example Output: OUTPSEGM (min/max per segment)**

<table>
<thead>
<tr>
<th>Segment</th>
<th>Min Pt Stimulus (Frequency)</th>
<th>Min Pt Value (dB)</th>
<th>Max Pt Stimulus (Frequency)</th>
<th>Max Pt Value (dB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1.9 GHz</td>
<td>−.99</td>
<td>2.12 GHz</td>
<td>2.12</td>
</tr>
</tbody>
</table>

Table 7-17 is an interpretation of the min/max data returned using the `SELSEG` and `OUTPSEGM` commands.

**NOTE**  A new Line Feed character <LF> is inserted after the segment number and after each data pair.

**Output Minimum and Maximum Point for All Segments**

Three GPIB commands allow the user to dump the min-or-max or min-and-max values for all active segments:

- **OUTPSEGAM**: outputs min and max data for each active segment.
- **OUTPAMIN**: outputs the min data for each active segment.
- **OUTPAMAX**: outputs the max data for each active segment.

The **OUTPSEGAM** output consists of:

- The total number of segments being reported.
- The following data for each segment:
  - segment number
  - min stimulus
  - min value
  - max stimulus
  - max value
Example:
Sending `OUTPSEGAM` may return the following:

```
5,
1, 1.900000000E+09, −9.900000E−01, 2.123456789E+09, 2.123456E+00
3, 2.300000000E+09, −10.00000E−01, 2.600000000E+09, 3.100000E+00
5, 3.200000000E+09, −10.00000E−01, 3.400000000E+09, 3.100000E+00
7, 4.300000000E+09, −10.00000E−01, 4.700000000E+09, 3.100000E+00
8, 5.000000000E+09, −10.00000E−01, 5.400000000E+09, 3.100000E+00
```

For an explanation of these results, see Table 7-18.

**NOTE**
A new line feed character `<LF>` is inserted after the segment number and after each data pair.

Table 7-18 is an interpretation of the min/max data returned using the `OUTPSEGAM` command.
Example Program of OUTPSEGAM Using BASIC

The following program is not included on the Programming Examples CD-ROM:

```basic
10 Minmax: !
20 Mm: IMAGE DD,":\",2X,D.DDDE,2X,SD.DDDE,2X,D.DDDE,2X,SD.DDDE
30 PRINT "TESTING: OUTPSEGAM: min/max points for each segment"
40 OUTPUT 716;"minmaxon;"
50 OUTPUT 716;"outpsegam;"
60 ENTER 716;Numsegs
70 PRINT "receiving data for";Numsegs;"segments"
80 FOR I=1 TO Numsegs
90 ENTER 716;Segnum,Minstim,Minval,Maxstim,Maxval
100 PRINT USING Mm; Segnum, Minstim, Minval,Maxstim,Maxval
110 NEXT I
```
Output Data Per Point

The GPIB command OUTPDATP returns the value of the selected point using FORM4 (ASCII). The point is selected using the SELPT command. This returns the last point if the selected point is out of range. Otherwise, it uses the same format as that used by the marker value command. These formats are as follows:

Table 7-19 Example Output: OUTPDATP (data per point)

<table>
<thead>
<tr>
<th>Display Format</th>

</tr>
</tbody>
</table>

* Value is insignificant, but is included in data transfers.

The commands in the following example are sent while using the format command LOGM.

Example:
Sending SELPT5 and OUTPDATP may return the following:

−3.513410E +00, 0.00915E +15 (Note that the second number is insignificant.)
Output Data Per Range of Points

The GPIB command OUTPDATR returns the value of the selected points using FORM4 (ASCII). This ASCII format requires many data bytes per point for transfer. For a large number of points, it may be faster to make trace data dumps (OUTPDATA) using a binary format. The range of points is selected using the SELMINPT and SELMAXPT commands (select minimum point, select maximum point of desired point range). These commands return the last max point if the selected points are out of range. Only the SELMAXPT will be returned if the selected minimum point is greater than the selected maximum point.

The commands in the following example are sent while using the format command LOGM.

**Example:**

Sending SELMINPT5, SELMAXPT7 and OUTPDATR may return the following:

3.880465E−01, 0.000039E−01
1.901648E−01, 1.363988E+11
5.57587E−01, 1.258655E+30 (Note that the second number is insignificant.)

For an explanation of these results see Table 7-20.

---

**NOTE**

A new line feed character \(<LF>\) is inserted after the segment number and after each data pair.

<table>
<thead>
<tr>
<th>Point</th>
<th>Value</th>
<th>Value*</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0.3880465</td>
<td>0.000039E−01</td>
</tr>
<tr>

<td>1.363988E+11</td>
</tr>
<tr>
<td>7</td>
<td>0.557587</td>
<td>1.258655E+30</td>
</tr>
</tbody>
</table>

* These values are insignificant.

Table 7-20 is an interpretation of the min/max data per range of points returned using the SELMINPT5, SELMAXPT7 and OUTPDATR commands.

Output Limit Pass/Fail by Channel

The GPIB commands OUTPLIM1 and OUTPLIM2 output the status of the limit test for channel 1 and channel 2, respectively.

These commands return the values 1 (PASS), 0 (FAIL), or −1 (NO_LIMIT) if limit testing is disabled. Currently, the results of limit testing can be retrieved by reading a bit in the status register.

**Example:**

Sending OUTPLIM1 or OUTPLIM2 (channel 1 or channel 2) may return the following:

1 (PASS), 0 (FAIL), or if limit test not enabled then −1 (NO_LIMIT).
A  Preset Conditions
Preset State

When the Preset key is pressed, the analyzer reverts to a known state called the factory preset state. This state is defined in the tables in this chapter. See “PRES” on page 1-183 and “RST” on page 1-212.
Table A-1 Analyzer Mode

<table>
<thead>
<tr>
